Acknowledgments

I would like to express my deepest gratitude from the core of my heart to all the imparts with the association of the scientific elite of the Indian Institute of Technology Guwahati, India. I would like to extend my heartfelt gratitude to all who have put an endless support and assistance directly or indirectly during my research journey and made it possible to submit this thesis.

First and foremost, I would like to express my special thanks and gratitude to **Dr. Akshai Kumar A. S.**, my Ph.D supervisor who gave me a wonderful opportunity to carry out my thesis work under his supervision. Thank you for introducing me to the field of pincer-metal catalysed organometallic chemistry and inspiring me to explore challenges in the research work and his continuous motivation, support, effective advice and suggestion helped me in achieving this feat of submitting my research work in the form of this thesis. I am continually motivated by his commitment to research, discipline and hard effort to get through challenging times and to complete my research work. I am also thankful to his family for loving, caring and support during my research journey.

- I am extremely thankful to the collaborator Prof. Biman B. Mondal and his precious suggestions during the research work.
- I am highly obliged to my doctoral committee chairman Prof. Biplab Mondal, along with the doctoral committee members Dr. Chandan K. Jana, and Dr. Chandan Mukherjee for their valuable time, inspiration, suggestions, and evaluation during my entire research period. I would like to thank Prof. Biplab Mondal, Prof. Jubaraj B. Bharua, Prof. Subhas C. Pan and Prof. Ashish Kumar Gupta for the interesting and informative courses they taught me as a part of my coursework. I also extend my thanks to all other faculty members of the Department of Chemistry, IIT Guwahati for their help and support.
- I am thankful to Dr. Babulal Das, Dr. Sิริyara Jagannatha Prathapa and my friends Sandeep Kumar for helping me analyze the single crystal XRD data for publication. I also thank my friend Shankhadeep Saha, Mrinmoy Roy for EPR and TGA analysis whenever I made an urgent request. My sincere thanks to Mr. Imdadul Islam and all the NMR operators of Department of chemistry, all the non-teaching staff our chemistry department, for their cooperation and help during my research progress. I am grateful to all the staff and operators of Central Instrument Facility (CIF), Nano Centre, North East

Centre for Biological Sciences and Healthcare Engineering (NECBH), IIT Guwahati. I sincerely admit IIT Guwahati for the financial support during my PhD work.

I am extremely blessed to have talented, passionate and friendly lab mates during my PhD tenure. I am very grateful to my senior Dr. Moumita Dutta, Dr. Kanu Das and Dr. Khadimul Islam for their mentorship during my initial days of research. I have learned everything from Kanu Das who helped me to set basement in organometallic chemistry. I have learned column chromatography from Khadimul Islam and Kanu Das. I extent my special thanks to Kanu Das who guided me to each point of my research work. I am very greatly to my colleague, my friend Vinay Arora, without him I can't imagine research because his assistance, support made my bad day to productive and fruitful. I am also taking the opportunity to thank my lab mates Dr. Lakshay Kathuria, Dr. Harsh Sharma, Ms. Himani Narjinari, Ms. Eileen Yasmin, Ms. Akshara Bisarya, Ms. Niharika Tanwar, Mr. Vikas, Mr. Bedabara Nag, Mr. Rounak Ranjit, Mr. Lalit Kumar Pandey, Mr. Babu Venkatesh, Ms. Susmita Das, Mr. Pabitra Maity, Mr. Soumen Maity, Bidhan Kar, Mr. Sudhanva, Mr. Dhiraj Mr. Kailas Mahipal Mr. Prasad Thombare, Mr. Jatin Gupta, Ms. Poonam Kumari, Mr. Pradhuman Kumar, Ms. Snata Deka, Ms. Tanima Pal for their valuable time and support during my research work.

- I highly obliged to MHRD and IIT Guwahati for providing me with the doctoral fellowship during my research work.
- I am grateful to all my respected teachers for their contributions to my education at different stages, without their education, I would not have been able to reach this stage of life. I would like to thank all of my respected teachers of Bidytirtha vidlaya, Gunananda Bati H.A.K.M High school, Jemo N.N High School, Kandi Raj College and Jadavpur university for their contributions to my passion for Chemistry. From the core of my heart I want to acknowledge my respected teacher Mr. Pallab Sinha who taught me physical science and from there I have started learning science. During My College days I used to go to stay their home due to my weak financial conditions. I also thankful to his family due to their unconditional love and motivated me all times. Specially, I am highly obliged to my chemistry teachers Mr. Palash Maitra, Mr. Tipurari Ghosh, Mr. Banshi Thakur, Dr. Nitty Gopal Mondal, Dr. Debaprasad Panda, Dr. Shouvik Chattyapadhya, Dr. Kajal Krishna Rajak, Dr. Tanurima Bhattyacharjee, Dr. Jnan Prakash Naskar. I have learned chemistry and loved chemistry from them. I want to extent my gratitude to my respected teachers Mr. Animesh Choudhury, Mr. Atanu

Bhattacharjee, Mr. Lakshman Kumar Ghosh, Mr. Kanak Joyti Roy, Mr. Debaditty Das, Mr. Anupam Roy, Mr Sukhen Das, Sukumar Ghosh, Jaydev Sarkar, Supravat Chattopadhyay for their motivation and financial support.

- I am grateful to Srijan Sujan (NGO) and Prerana The Inspiration (NGO) and all the members of Srijan Sujan specially Mr. Abhijit Sengupta for their financial support and motivation.
- I want to express my gratitude to my childhood, school and college friends. Especially I want to acknowledge my friends Palash Nandi, Rajarshi Pal, Niladri Sekhar Mondal, Souvic Mishra, Gopal Ghosh, Suhas Kundu, Budhadeb Konai, Anirban Ghosh, Amit Garai, Taraknathnath Mondal, Nanda Gopal Bar, Paramita Saha, Sanu Saha, Priyanka Halder, Partha Pratim Kayal, Parinita Singhamahapatra, Anushree Medda, Roumi Patra, Anup Kumar Ghosh, Arnab Bisuei, Monimala De, Indrajeet Giri, Shubhajit Mondal, Bitan Sardar, Achena saha, Payel Mukherjee, Ahsish Ghosh, Rajesh Das, Rounak Jahan, Pallabi Thakur, Subhasish Malakar, Sanghamitra Sarkar, Saikat Mondal, Pintu Nusipuri, Kamal Hossen, Nadeem Khan, Udita Mishra, Anirudra Mishra, Rahul mondal, Bikash Mondal, Shubhajit Mondal for their time, valuable suggestions and mentally support during my Ph.D period.
- I want to acknowledge all my PhD batchmates; Dr. Pallab Karjee, Dr. Jitendra Nath, Tanumoy Sarkar, Bapan Samanta, Bikoshita Parashar, Priyanka Adhikari, Bittu Lama, Dr. Rinki Brahma, Dr. Sabina Yashmin, Rahul Sharma, Debjoyti Pal, Indraneel Debnath, Tirupati Roy, Sagnik dey, Samir Roy, Dr. Chan, Dr. Hrishikesh Kalita, Dr. Priyanka Sarkar, Dr. Riya Sinha, Dr. Arin Bhagat, Rajdikshit Gogoi, Sourav Mondal, Somnath Paik, Partha Pratim Nath for making my days memorable in IITG.
- I have some special friends in my life who have always supported me at difficult times, and words cannot explain how much I appreciate them. I extremely show my gratitude to Vinay Arora, Mrinmoy Roy, Monoranjan Konwar, Shankhadeep Saha, Sujay Pal Nanda Gopal Bar, Anirban Ghosh, Amit Garai, Roumi patra from the inner core of my heart. There are ups and down in life, but some friend is always special in life. I express my gratitude to DimpY Dey and her family.

- Words cannot express my gratefulness to my colleagues, juniors and seniors especially Dr. Debasish Barman, Dr. Mihir Manna, Dr. Ashesh Das, Dr. Payel Dewari, Dr. Chandan Gharui, Dr. Gobinda Doloi, Dr. Sandeep Mondal, Dr. Basab Kanti Das, Dr. Abhijeet Mondal, Dr. Nirmallya Bandhyapadhyaya, Dr. Bharghav Guhathakurtha, Dr. Sandeep Choudhury, Dr. Ipsita Mondal for their time, valuable suggestions during my Ph.D period.
- I could not have started this journey without the help of Academic Section, Student Affairs and R&D Section of IIT Guwahati.
- My sincerest thanks to Doctors and staffs of IIT Guwahati hospital for their caring
- This endeavor would not have been possible without my Ph.D. batchmates, seniors and juniors who helped directly or indirectly during my research.
- My heartfelt gratitude goes to my parents (Abharani Naandi, Rabindranath Nandi), sister (Krishna Mondal), brother (Gautam Nandi, Uttam Nandi, Budhdeb Nandi), and brother-in-law (Debasish Mondal), Sister-in-law (Debashri Das, Soumitra Nandi), Uncles (Abhimannu Nandi, late Chinmoy Nandi), aunts (Vanumati Nandi, Parvati Nandi), cousin (Radharani Nandi) who have always supported and motivated me through all of my ups and downs days. Without their immense patience, good wishes, and great sacrifice, I would have not been able to complete my doctoral studies. Thank all for all the unconditional love, care, and sacrifices that have shaped my life. Without their well wishes and blessings, I would not have been able to reach this stage and complete my doctoral studies. I would like to express my greetings to all my family members and relatives.
- It's very tough to fit all the names into a single paper; any absence in this brief acknowledgment does not imply a lack of gratefulness. I acknowledge all of them from whom I was being helped.
- Finally, I bow down to the almighty God for blessing, protecting, and guiding me throughout this period. I could never have accomplished this without the faith I have in the almighty. Thank you Kanha. Thank you Gopu. Thank you, Om Nama Shivai, Har Har Mahadev. Radhe Radhe. "Hare Krishna Hare Krishna Krishna Krishna Hare Hare Hare Rama Hare Rama Rama Rama Hare Hare".

Department of Chemistry

Declaration

I do hereby declare that the research work embodied in this thesis entitled “*Pincer-Ruthenium and Pincer-Cobalt Catalyzed Value-Addition of Alcohols*” has been carried out by me in the Department of Chemistry, Indian Institute of Technology Guwahati, Assam-781039, India, under the supervision of **Dr. Akshai Kumar A. S.** for the award of the degree of doctor of philosophy and it has not been submitted elsewhere for the award of any degree or diploma.

In keeping with the general practice of reporting scientific observation, due acknowledgments have been made wherever the work described is based on the findings of other investigators.

Abstract

The contents of the present thesis entitled “**Pincer-Ruthenium and Pincer-Cobalt Catalyzed Value-Addition of Alcohols**” have been divided into five chapters based on the results achieved from the experimental and computational work carried out during the entire course of the PhD research program.

Chapter I discusses a brief description on catalytic organic transformations reported in literature utilizing pincer-metal complexes. A large library of pincer-complexes that have been studied for various reactions such as alkane dehydrogenation, C-C or C-N bond formation and reduction of carbon dioxide, have been briefly reviewed in the chapter. The chapter ends with the identification and scope of the current thesis.

Chapter-II discusses the synthesis and characterization of three novel NNN pincer-Ru complexes based on *bis(imino)pyridine* ligands. These complexes along with other previously reported pincer-Ru complexes based on *bis(imino)pyridine* and *2,6-bis(benzimidazol-2-yl)pyridine* ligands have been studied for the β -methylation of 2-phenylethanol and the selective β -dimethylation of 1-phenylethanol utilizing methanol as an alkylating agent. The optimization studies revealed that the pincer-ruthenium complex $[(^{\text{MeBim}2}\text{NNN})\text{RuCl}(\text{PPh}_3)_2]\text{Cl}$ is the most efficient among the considered catalysts. In the presence of 0.5 mol % of $[(^{\text{MeBim}2}\text{NNN})\text{RuCl}(\text{PPh}_3)_2]\text{Cl}$, 0.75 equivalents of KOH and 7.5 equivalents of methanol, up to 92% yield of β -methylated 2-phenylethanol was observed at 140 °C after 24 h. Under similar conditions, the β -dimethylation of 1-phenylethanol was achieved using 2 equivalents of Na and 24.8 equivalents of methanol. The synthetic protocol was further extended towards the β -methylation and selective β -dimethylation of about 35 substrates. The evidence for the homogeneous nature of the reaction was revealed from mercury drop experiments and kinetic studies. From the kinetic studies, it was observed that the rate of product formation has a linear dependence on the concentrations of both the pincer-ruthenium catalyst and 2-phenylethanol. DFT studies are in line with the observed secondary kinetic isotope effect (KIE) of 1.56 and suggest that dehydrogenolysis involving σ -bond metathesis of methanol with the Ru-H species leading to the evolution of hydrogen is the RDS with a barrier of 24.06 kcal/mol. The NMR and HRMS analysis have shown the presence of pincer-Ru-H and pincer Ru-OMe species, which are the lowest-energy intermediates of the catalytic cycle and are likely to be the resting states of the catalytic cycle.

Chapter-III formulates the decarboxylative coupling of alcohols to alkanes employing a plethora of new and known NNN pincer-Ru complexes of the type $(R^2NNN)RuCl_2L$ ($R = iPr, tBu, Cy, Ph, p-F-C_6H_4, p-OMe-C_6H_4$ and $L = PPh_3, CO$ and CH_3CN) based on *bis(imino)pyridine* ligands and $[(^{RBim^2}NNN)RuClL_2]Cl$ ($R = H$ and $Me, L = PPh_3$ and CO) based on 2,6-*bis(benzimidazole-2-yl)pyridine* ligands. Notably, among the considered pincer-Ru complexes and their Ru precursors, a majority were either not very active or were unselective giving alkene/alkane mixtures. However, in the presence of 0.5 equivalents of NaOH in toluene at 140 °C, the complex $(^{MeBim^2}NNN)RuCl_2(PPh_3)_2$ based on 2,6-*bis(benzimidazole-2-yl)pyridine* ligand gave excellent activity affording up to 91% yield of alkane (1,3-diphenyl propane) with 100% selectivity within 5 h of reaction. Experimental mechanistic studies point to the generation of hydrogen (detected by GC) and formic acid (detected by 1H NMR) during the reaction along with involvement of organic intermediates such as α,β -unsaturated aldehydes. The $[(^{MeBim^2}NNN)RuCl(PPh_3)_2]Cl$ catalyzed transformation of 2-phenyl ethanol to 1,3-diphenyl propane demonstrated a first-order dependence of initial rate on both the catalyst concentration and the concentration of base. While catalyst poisoning experiments using mercury revealed the homogeneous nature of the catalyst, a few of these molecular species including the resting state $[(^{MeBim^2}NNN)RuH(PPh_3)_2]Cl$ have been detected by HRMS analysis and NMR studies. The experimental studies are nicely complemented by the DFT studies, that indicate the dehydrogenolysis step leading to the formation of 2-phenyl acetaldehyde and the resting state $(^{MeBim^2}NNN)RuHCl$ (experimentally trapped as PPh_3 adduct) to be the rate-determining step with a barrier of 22.81 kcal/mole at 140 °C. Furthermore, the corresponding cycle with the least active catalyst $(^{iPr^2}NNN)RuCl_2(PPh_3)$ that gave 14% yield of 1,3-diphenyl propane at 25% selectivity, involved insertion of 1,3-diphenyl propene into the Ru-H bond as the RDS that was kinetically unfavorable by 5 kcal/mole in comparison to the rate-determining dehydrogenolysis step of the cycle involving most active catalyst $[(^{MeBim^2}NNN)RuCl(PPh_3)_2]Cl$. This work elaborates the direct access to jet-fuel-grade 1,3-diphenyl propane starting from 2-phenyl ethanol in a single-step one-pot reaction and offers great promise to open up exciting opportunities in this very important field of study.

Chapter-IV deals with the catalytic β -alkylation of alcohols using inexpensive and readily available cobaltous chloride under aerobic conditions at 140 °C. At higher loadings of cobaltous chloride (1 mol%) in the presence of 2.5 mol% NaO^tBu, there is an instant formation of heterogeneous Co nanoparticles (NPs) which are apparently air-sensitive and lead to poor yields (*ca.* 25%) of β -alkylated products. On the other hand, performing the reaction in an inert

atmosphere under otherwise identical conditions resulted in higher yields (*ca.* 44%). The heterogenization and gradual loss of activity in air could be mitigated by operating at a lower (0.01 mol%) CoCl₂ loading in the presence of 2.5 mol% NaO^tBu at 140 °C. Under these conditions, the catalytic β -alkylation of alcohols afforded high yields (up to 89%) and unprecedented turnovers (*ca.* 8900) of the desired product. Mechanistic studies are indicative of the involvement of catalysts based on *in-situ* generated molecular Co complexes of alcohols. The involvement of C–H activation is confirmed by the deuterium labelling experiments, where a KIE of 1.61 was obtained. Kinetic studies indicate linear dependence of the rate on the concentration (in the regime of homogeneity) of cobaltous chloride and sodium *tert*-butoxide along with a non-linear dependence on the concentration of both the substrates.

Chapter-V describes the synthesis of pincer complexes of the type (R²NNN)CoCl₂ (R = *i*Pr, ^tBu, Cy, Ph, *p*-F-C₆H₄) derived from the inexpensive base metal cobalt. Among these complexes, (^{*i*}Pr₂NNN)CoCl₂ was found to be highly active for the catalytic β alkylation of alcohols in air at 140 °C. While the pincer-Co (0.0025 mol %) catalyzed β - alkylation in the presence of NaO^tBu (2.5 mol %) took 24 h (85%, 34000 TON at 1417 TO/h) under conventional heating (140 °C), the corresponding reaction under microwave conditions (140 °C at 75 W) was complete in only 2 h with comparable yields (83%, 33200 TON), but with a better TOF (16600 TO/h). In contrast, CoCl₂ (0.0025 mol %) under similar conditions results in lower yields under both conventional (66%, 26400 TON at 1100 TO/h) and microwave heating (61%, 24400 TON at 12200 TO/h). The catalytic system has been successfully implemented (39 examples) to accomplish the β -alkylation of various secondary alcohols with several primary alcohols. EPR studies and magnetic moment measurements using the Evans method demonstrate that Co remains in its +2 oxidation state and in an octahedral geometry throughout the reaction. Significant evidence for the involvement of β - hydride elimination leading to acetophenone in the RDS of the pincer-Co catalyzed β -alkylation is obtained from competitive deuterium labelling experiments, which are indicative of a KIE of 6.14. The current report on base-metal catalysis in air under microwave conditions that leads to high yields of β -alkylation with unprecedented turnovers (33200 TON at 16600 TO/h) in a very short time (2 h) offers exciting atom-economical and greener possibilities for these class of synthetically valuable Guerbet-type reactions.

Chapter- I

Pincer-Metal Complexes and Their Applications

1.1. Pincer complexes

The term “pincer” represents one of a pair of curved claws of an animal such as a crab. In organometallic chemistry, the pincer complex represents a tridentate ligand coordinated to the metal. The tridentate (pincer) ligand behaves as a chelating ligand where the three binding atoms are coplanar in a meridional fashion (as shown in Figure 1.1).¹ The three binding atoms typically are N/P/C/S/O and the combination of ligating atoms are PCP, NCN, NNN, PNP, PCN, PNO and SCS. The unique chelating properties of pincer ligands imparts rigidity to the metal-ligand complex and the steric and electronic environments of the pincer framework results in the high selectivity in the catalytic reactions. Also, in certain cases the metal-ligand co-operation imparts stability to the metal complex. Tridentate pincer ligand frameworks strike an optimal balance between stability and reactivity.²⁻⁶

Shaw and Moulton were the first ones who developed meridional tridentate systems with central anionic carbon attached by two *tert*-butyl phosphine units which is now famously abbreviated as $t\text{Bu}^4\text{PCP}$.³ In 1989, van Koten coined the term “pincer” to refer to such tridentate systems.

Figure 1.1. Schematic representation of a pincer metal complex representing the variable parameters.

The treatment of $t\text{Bu}^4\text{PCP}$ ligand (**1.1**) with metal salt resulted in C-H activation at the *ipso* position of the $t\text{Bu}^4\text{PCP}$ ligand (Scheme 1.1).^{12, 13} The reaction of group **IX** and **X** metal salts with the $t\text{Bu}^4\text{PCP}$ resulted in the formation of hydrido-chloride complexes (**1.Rh1** and **1.Ir1**) and chloride complexes (**1.Ni1**, **1.Pd1**, **1.Pt1**) respectively (scheme 1.1). The synthesis of the pincer-metal complex depends on the nature of the donor atoms, nature of the ligand backbone, the solvent's polarity and hybridization of the *ipso*-atom.

Pincer complexes has been modified by varying the ligating group or the linkers atoms depending on the various reaction requirements.^{6, 16, 17} The electronic properties can be tuned

Scheme 1.1. Initial report on PCP pincer-metal complexes.^{14, 15}

by controlling the carbon *para* to the *ipso* carbon. Several polar functional groups could be placed on the *p*-carbon which provide an option to heterogenize the catalytic system on any solid support.¹⁸ The application of pincer complexes are vast, which has been studied and applied using various pincer frameworks.^{19, 20} Depending on the co-ordinating ligand framework the pincer complexes has been generalized as PCP,²¹ PNP,²²⁻²⁴ PCN,²⁵ PNN,^{24, 26, 27} NCN,^{21, 28} NNN,²⁹⁻³¹ CNC.^{32, 33} Some of the selected examples of different types of pincer complexes are shown in Figure 1.2.

Pincer-metal catalyst plays a pivotal role in obtaining access to several synthetically challenging organic products, commodity chemicals,⁷ fine chemicals,⁷ fuels,⁷ pharmaceuticals, and agrochemicals. Pincer complexes have been widely used as catalysts for hydrogenation,⁸ dehydrogenation,⁸ hydrofunctionalization⁸ and activation of CO₂⁹ to CH₃OH as well as N₂¹⁰ to NH₃. The transformation of alcohols which are readily available from bio-mass to several value-added chemicals and fuels are also accomplished using pincer-metal catalysts.⁷ Alcohols prove to be versatile feedstock materials for numerous organic transformations in chemical enterprises. Of particular interest are their utility in new C-C bond formations where they can be employed as a substitute of carbon source in hydrocarbon-based chemical industries and petrochemical industries. The traditional methods of synthesizing C-C bonds involve alkyl halide as alkylating agent with alcohols,⁹ but these methods produce lot of waste products and it requires expensive reagents which are toxic in nature. Among the various protocols, the one where β -alkylation of alcohols have been employed to form C-C bond, catalyzed by transition metals have gathered huge attention.¹¹ Formation of higher β -alkylated alcohols *via* acceptorless dehydrogenative coupling of alcohols proves to be an environmentally benign process. Pincer-based metal complexes have been majorly employed for such transformations and the reports are crowded with precious metals having phosphine-based ligand systems.¹⁰

Figure 1.2. Different types of pincer-metal complexes reported in literature.

1.1.1. Catalytic application of various pincer-metal complexes

1.1.1.1. Alkane dehydrogenation reaction

Olefins are key chemical intermediates that may be converted to amines, alcohols, alkyl halides, aldehydes, ketones and esters or enchain into polymers with various commercial applications.⁷ Pincer metal complexes play a huge role to convert the alkanes to the corresponding alkenes.

Figure 1.3. Pincer-Ir complexes reported for alkane dehydrogenation.

In 1996, Kaska and Jensen reported the use of PCP pincer-iridium complex ($(^{t}\text{Bu}^4\text{PCP})\text{IrH}_2$ (**1.Ir3** = **1.Ir2-H2**)) as catalyst for the alkane transfer dehydrogenation (Figure 1.3).³⁴ The **1.Ir3** exhibited excellent activity for the dehydrogenation of COA that is driven by the periodic addition of TBE (increments of 0.4 M) at an elevated temperature (200 °C) giving up to 1000 TOs at 12 TON/min. Later, Kaska, Jensen and Goldman investigated that the **1.Ir3** (1 mM) itself catalyzed the dehydrogenation of cyclodecane without any acceptor and yielded 360 TON in 24 h at 200 °C.³⁵ Subsequently, Goldman group developed a active catalyst ($(^{i}\text{Pr}^4\text{PCP})\text{IrH}_4$ (**1.Ir4** = **1.Ir5-H4**)) for the acceptorless cyclodecane dehydrogenation. The dehydrogenation of cyclodecane proceeded *via* double dehydrogenation of cyclodecene followed by isomerization to give *trans, trans*-1,5 cyclodecadiene which subsequently underwent a Cope rearrangement to give *trans*-1,2-divinylcyclohexane. This *trans*-1,2-divinylcyclohexane acted as hydrogen acceptor to complete the catalytic cycle with a net production of diethylcyclohexane from cyclodecane (Scheme 1.2).⁷

Scheme 1.2. Net isomerization of cyclodecane to diethylcyclohexane, catalyzed by ($(^{i}\text{Pr}^4\text{PCP})\text{Ir}$).

Goldman has performed a detailed study on the effect of substituents in the catalytic dehydrogenation of alkanes. The bulkiness of the substituents hindered the progress of the reaction. In spite of the ‘pincer effect’ the bulkiness of the *tert*-butyl groups inhibits H_2 addition, i.e intermediates of dehydrogenation cycle are more favoured by isopropyl groups whereas it is sterically disfavoured by the *tert*-butyl groups. On this basis, the dehydrogenation of cyclooctane is more favoured with ($(^{i}\text{Pr}^4\text{PCP})\text{IrH}_2$ (**1.Ir5-H2**)) than with ($(^{t}\text{Bu}^4\text{PCP})\text{IrH}_2$ (**1.Ir2-H2**)).³⁶ The dehydrogenation of cyclooctane was carried out with both **1.Ir2-H2** and **1.Ir5-H2** at 150 °C at a similar loading of 1 mM). While in the case of **1.Ir5-H2** more than 94 TON was achieved, only 11 TON was obtained when **1.Ir2-H2** was used (Table 1.1). The rate of

acceptorless dehydrogenation rate is more for cyclodecane that has a high reflux temperature of 201 °C than that of low boiling cyclooctane (b.p 149°C). The **1.Ir5-H₂** catalyzed the cyclodecane dehydrogenation to cyclodecene with a *cis: trans* ratio of 4.6:1 with 460 TON after 1h. In case of **1.Ir2-H₂** lower TON of 170 after 4h was observed.³⁶

Table 1.1. Dehydrogenation of cyclooctane with **1.Ir2** and **1.Ir5**

entry	catalyst [1.0 mM]	time	TON
1	1.Ir2-H₂	1 h	11
2	1.Ir5-H₂	30 min	47
3	1.Ir5-H₂	1 h	>94
4	1.Ir5-H₂	15 h	105

In 1999, Goldman reported the acceptorless dehydrogenation of *n*-alkanes with homogeneous catalyst **1.Ir5-H₂** that resulted in a mixture of internal isomers.³⁷ The catalyst (^{*i*}Pr⁴PCP)IrH₂ (**1.Ir5-H₂**) showed high efficiency for acceptorless dehydrogenation of *n*-alkanes compared with (^{*t*}Bu⁴PCP)IrH₄ (**1.Ir2-H₄**) and both the catalysts were selective towards 1-octene in the *n*-octane/1-decene transfer dehydrogenation at 150 °C. While (^{*i*}Pr⁴PCP)IrH₂ (**1.Ir5-H₂**) showed higher catalytic efficiency than (^{*t*}Bu⁴PCP)IrH₄ (**1.Ir2-H₂**), the latter showed higher selectivity than the former in the catalytic transfer dehydrogenation of *n*-octane/1-decene at 150 °C.

For the COA/TBE and *n*-octane/NBE dehydrogenation, Yamamoto developed fused tricyclic 7-6-7 type pincer-Ir complex (7-6-7^{R4}PCP)Ir (**1.Ir13**, R = ^{*i*}Pr ; **1.Ir14**, R = Cy; **1.Ir15**, R = Ph) complexes (Figure 1.4)³⁸. These types of catalysts are highly efficient due to their flexible backbone and their fused nature of the bonds imparts rigidity and thermal stability to the iridium complex. The dehydrogenation rate of COA/TBE (1:1) was higher at both low and high temperature with phenyl analogue **1.Ir15**, while with the isopropyl analogue **1.Ir13**, the rate was higher only at high temperature. The catalyst **1.Ir15** showed a maximum of 4100 TON after 24 h at 200 °C for the transfer dehydrogenation of COA/TBE (1:1). In the case of *n*-octane/NBE dehydrogenation, **1.Ir13** showed higher activity compared with **1.Ir15** due to the poor solubility of **1.Ir15** in *n*-octane.

Scheme 1.3. Transfer dehydrogenation of *n*-octane catalyzed by **1.Ir2-H₂** and **1.Ir5-H₄**.

In a similar fashion, Kaska and co-workers developed tricyclic (PCP)-Ir complex (^{*t*}Bu⁴Anthraphos)Ir, **1.Ir17** for the acceptorless dehydrogenation of alkanes (Figure 1.4).³⁹ The complex **1.Ir17** was thermally stable up to 250 °C due to its high rigidity. Later, Goldman and Brookhart observed that the isopropyl analogue (^{*i*}Pr⁴Anthraphos)Ir, **1.Ir16** (Figure 1.4) was very effective towards alkane dehydrogenation^{40, 41}.

Figure 1.4. Fused tricyclic PC(*sp*²)P pincer-Ir complexes reported for alkane dehydrogenation.

Brookhart and Jensen⁴²⁻⁴⁵ independently developed (^{*R*}POCOP)Ir type pincer complexes for dehydrogenation of alkanes (Figure 1.5). The reactivity in alkane dehydrogenation was changed due to introduction of heteroatom such as O, S in place of CH₂ of the PCP ligand framework. For the COA/TBE dehydrogenation, the catalyst (^{*t*}Bu⁴POCOP)Ir (**1.Ir19**) (1583 TONs after 40 h) is more active than (^{*t*}Bu⁴PCP)Ir (**1.Ir2**) (230 TONs after 20 h). However, for

the dehydrogenation of linear alkanes, (^tBu⁴POCOP)Ir (**1.Ir19**) was less effective catalyst compared to (^tBu⁴PCP)Ir (**1.Ir2**).⁴²

Brookhart and co-workers tested fluoro containing pincer complexes (*p*-F-^tBu⁴POCOP)Ir (**1.Ir24**) and (*p*-C₆F₅-^tBu⁴POCOP)Ir (**1.Ir25**) for the COA/TBE (1:1) dehydrogenation at 200 °C. The catalyst (*p*-F-^tBu⁴POCOP)Ir (**1.Ir24**) (1530 TONs after 40 h) showed comparable activity with (^tBu⁴POCOP)Ir (**1.Ir19**), whereas (*p*-C₆F₅-^tBu⁴POCOP)Ir (**1.Ir25**) showed a higher activity (2041 TONs after 40 h) (Figure 1.5).

Figure 1.5. PYCZP pincer-iridium complexes studied for alkane dehydrogenation.

Huang and co-workers observed that (ⁱPr⁴PSCOP)Ir (**1.Ir23**) catalyzed the transfer dehydrogenation of COA/TBE (1:1) at 200 °C with at the rate of 2900 TOh⁻¹ but for the similar reaction (ⁱPr⁴POCOP)Ir (**1.Ir18**) showed 6900 TOh⁻¹ whereas for (^tBu⁴PCP)Ir (**1.Ir2**) TOF of 1200 TOh⁻¹ was observed.⁴² In case of (^tBu⁴POCOP)Ir (**1.Ir19**) the dehydrogenation reactions levelled off after 6 h with only 62% conversion but (ⁱPr⁴PSCOP)Ir (**1.Ir18**) catalyzed the dehydrogenation reactions with complete consumption of TBE after 8 h.

Huang reported 1400 TOh⁻¹ in the (ⁱPr⁴PSCOP)Ir (**1.Ir23**) catalyzed *n*-octane dehydrogenation using 0.5 M TBE, whereas (^tBu⁴POCOP)Ir (**1.Ir19**) and (^tBu⁴PCP)Ir (**1.Ir2**) demonstrated 220 TOh⁻¹ and 820 TOh⁻¹ respectively under identical conditions. Both (ⁱPr⁴PSCOP)Ir (**1.Ir23**) and (^tBu⁴PCP)Ir (**1.Ir2**) showed similar regioselectivity (30%) at comparable TON of 115.

Wendt group reported an efficient transfer dehydrogenation of COA/TBE (1:1) with ((*m*-CF₃)₂-^tBu⁴POCOP)Ir (**1.Ir29**) at 170 °C⁴⁶. The catalyst (*p*-((*m*-CF₃)₂C₆H₃)^tBu⁴POCOP)Ir

(**1.Ir28**) achieved 2070 turnovers after 40 h at 200 °C for the transfer dehydrogenation of COA/TBE (1:1). While the catalyst (*p*-((*m*-CF₃)₂C₆H₃)^{*t*Bu}POCOP)Ir (**1.Ir28**) showed lower activity than ((*m*-CF₃)₂-^{*t*Bu}POCOP)Ir (**1.Ir29**), it showed comparable activity as (*p*-C₆F₅-^{*t*Bu}POCOP)Ir (**1.Ir25**) (Figure 1.5) ⁴².

Figure 1.6. Fluorine containing POC(*sp*²)OP pincer-Ir complexes reported for alkane dehydrogenation.

Over the last 4 decades, the catalytic alkane dehydrogenation using pincer metal complexes of group 9 has been extensively studied. In particular, pincer-iridium complexes played the most vital role as a catalyst for the transfer dehydrogenation of alkanes, demonstrating high TON and excellent regioselectivity. The pincer-iridium catalyzed dehydrogenation has various applications depending on substrates and acceptors. In the transfer dehydrogenation, the lighter alkene plays a dual role as both a sacrificial acceptor and a dienophile in subsequent Diels-Alder cyclization, leading to the production of various precious BTX-chemicals.^{46b} The alkyl group in cross metathesis selectively produces industrially valuable linear *n*-alkyl arenes.^{46b} Additionally, the direct functionalization of alkyl-boronate esters, silanes, linear alkyl amines and linear alkyl aldehydes has also been achieved.^{46b} However, achieving high yield of α -olefins starting from alkane remains a significant challenge. Though there are a plethora of pincer-metal catalysts based on Ir,^{46b-c} Rh,^{34,46d} Ru^{46e} that have been reported for alkane dehydrogenation, only few of them has been discussed here to provide a glimpse of utility of pincer complexes in accomplishing this chemistry.

1.1.1.2. Reduction of CO₂

Carbon dioxide (CO₂) is a green-house gas and use of CO₂ as a renewable and cost-effective

C1 building block has received increasing attention from the scientific point of view in recent years.⁴⁷⁻⁵³ The activation of CO₂ is very challenging due its high thermal and kinetic stability.⁵⁴⁻⁵⁶ Hydrogenation of CO₂ leads to several useful chemicals like methanol, methane, formaldehyde and formic acid that are versatile starting materials to fuels and fine chemicals. In 1976, Hashimoto and co-workers first reported CO₂ hydrogenation to formic acid and its derivatives by using group VIII transition metal catalysts.^{57a} Later, various methodologies were developed for the value-addition of CO₂ using homogeneous^{57a} as well as heterogeneous^{57b} catalytic systems.

For the first time, in 2009 Nozaki and co-workers carried out the hydrogenation of CO₂ with a pincer complex.⁵⁸ They developed PNP-Ir (**1.Ir30**) catalyst for the hydrogenation of CO₂ to formate salts at 60 bar (CO₂ : H₂ = 1:1) with 3,500,000 TON (Scheme 1.4).⁵⁸ Later, Hazari group introduced a new iridium complex **1.Ir31** for the hydrogenation of CO₂ to formate salt with 348000 TON at 55 bar (CO₂ : H₂ = 1:1) (Scheme 1.4). In 2011, Milstein and co-workers reported PNP pincer-iron complex **1.Fe1** and used it for the conversion of NaHCO₃ to sodium formate in the presence of molecular hydrogen (8.3 bar) and achieved 320 TON. This catalyst also demonstrated activity for the hydrogenation of carbon dioxide in the presence of molecular hydrogen under 10 bar of CO₂ and H₂ (2:1) and it produced formate with 788 TON (Scheme 1.4).⁵⁹ In 2015, Pidko and co-workers used **1.Ru9** for the hydrogenation of CO₂ to formate salt and obtained 1100000 TON at 40 bar (CO₂ : H₂ = 1:1) (Scheme 1.4).⁶⁰

Scheme 1.4. Some initial reports on CO₂ hydrogenation by pincer-metal catalysts.

In 2015, Bernskoetter and co-workers reported iron catalyzed CO₂ hydrogenation to formate salt (Scheme 1.5).⁶¹ The catalyst **1.Fe2** showed the best result with 58990 TON whereas **1.Fe3**

(TON 46110) and **1.Fe5** (TON = 46130) exhibited almost similar activity. In contrast, **1.Fe4** catalyzed the hydrogenation of CO₂ with little less activity and exhibited TON of 38970 (Scheme 1.5).

Scheme 1.5. Hydrogenation of CO₂ catalyzed by (PNP) pincer-iron complexes reported by Bernskoetter⁶¹

In 2016, hydrogenation of CO₂ with pincer catalyst was reported by Bernskoetter and co-workers. They developed PNP pincer-cobalt catalyst for the hydrogenation of CO₂ to formate as shown in Scheme 1.6.⁶² The catalyst **1.Co2** showed quite high TON of 29000 (TOF = 5700 h⁻¹) with LiOTf as Lewis acid and DBU as a base. In the presence of Lewis acid, formate anion dissociated from metal centre,⁶¹ but in absence of Lewis acid, catalytic activity decreased significantly, resulting in a TON of 460. Furthermore, the addition of one equivalent of ligand in the catalytic reaction mixture stabilized the metal complex and resulted in an increased TON. The analogous complexes of **1.Co2**, namely **1.Co3** and **1.Co4** were also employed for the hydrogenation of CO₂ as shown in Scheme 1.6. The catalyst **1.Co3** with a cyclohexyl ligand displayed similar catalytic activity as **1.Co2** with TON of 24000, whereas its NH analogue **1.Co4** displayed lower TON of 450.

A hypothetical catalytic mechanism for hydrogenation of CO₂ was proposed using **1.Co2** as shown in Scheme 1.7.⁶² The complex **1.Co2** reacts with H₂ to form an intermediate **1.Co2a**. In presence of base DBU, **1.Co2a** could be deprotonated to monohydride cobalt complex **1.Co2b**

Scheme 1.6. Hydrogenation of CO₂ catalyzed by (PNP) pincer-cobalt complexes.⁶²

and it could reversibly converted to **1.Co2c** with loss of one molecule of CO or react with CO₂ to form formate-coordinated cobalt intermediate **1.Co2d** *via* insertion mechanism. In the last step, dissociation occurs to produce the formate anion while regenerating **1.Co2**.⁶²

Scheme 1.7. Proposed mechanism for CO₂ hydrogenation using homogenous pincer-cobalt catalyst **1.Co2**.⁶²

Recently in 2024, Ahmed and co-workers developed (CNC) carbene pincer-cobalt(I) complex for the hydrogenation of CO₂ to formate salt with 39800 TON (Scheme 1.8).⁶³

Overall, significant progress has been made for the hydrogenation of CO₂ to formic acid using

Scheme 1.8. Hydrogenation of CO₂ catalyzed by (CNC) pincer-cobalt(I) complex.⁶³

homogeneous pincer complexes, few of which have been discussed above.^{61,62} For CO₂ hydrogenation, utilizing inexpensive and earth-abundant metals that exhibit greater catalytic activity than their precious metal counterparts present a promising solution in near future.

1.1.1.3. Catalytic fixation of nitrogen gas to ammonia

Catalytic nitrogen fixation is an essential chemical revolution and one of the most important and challenging transformations.¹⁰ The development in this field made with the molecular complexes has enabled the formation of the bioactive form of NH₃ from N₂.¹⁰ The conventional Haber-Bosch methods requires very high pressure of 150-250 bar and high temperature of 400-500 °C for the transformation of N₂ to NH₃ which has very high demands in terms of cost.¹⁰ In order to accomplish this very important transformation under milder conditions, there has been numerous efforts on development of homogeneous catalytic systems.¹⁰

In 2010, in a first example of a pincer catalyst for the N₂ to NH₃ reaction, Nishibayashi and co-workers introduced dinuclear molybdenum complex for molecular nitrogen fixation (Scheme 1.9).⁶⁴ The N₂ reduction was carried out in toluene at room temperature with [LuH]OTf (96 equivalents) and Cp₂Co (72 equivalents) as a proton and electron source respectively with **1.Mo1** as (pre)catalyst which resulted in 6.9 equivalents of NH₃ per Mo. Upon increasing the acid ([LuH]OTf) to 266 equivalents and reductant Cp₂Co to 72 equivalents, the NH₃ production increased to 11.6 equivalents per Mo. The substituents present on the phosphorous atom had significant influence on the PNP coordination mode, that has resulted in vast changes in the activity of the catalytic reaction.⁶⁵ While the (pre)catalyst **1.Mo2** with *tert*-butyl on one phosphine arm and phenyl on the other phosphine arm provided 2 equivalents of NH₃ per Mo,

1.Mo3 flanked with *tert*-butyl phosphine and adamantyl phosphine produced 14 equivalents of NH₃ per Mo (Scheme 1.9).⁶⁵

Scheme 1.9. The first report on pincer-Mo catalyzed activation of N₂ by Nishibayashi.^{64, 65}

In 2017, Schrock and co-workers developed a geometrically distinct pincer ligand framework of diamido(pyridine) for N₂ fixation using Mo.⁶⁶ The catalyst **1.Mo4** in the presence of 108 equivalents of [Ph₂NH₂]₂OTf and 54 equivalents of Cp*₂Co produced 1.3 equivalents of NH₃ (Scheme 1.10).⁶⁶ The use of a large excess of base and Cp*₂Co is the drawback of this protocol. Furthermore, upon using the *tert*-butyl methoxy substituted catalyst **1.Mo5** under similar reaction conditions, a significant enhancement in the yield of NH₃ (7.9 equivalents) was observed (Scheme 1.10).⁶⁶

Scheme 1.10. Mo catalyzed activation of N₂ by Schrock.⁶⁶

Nitrogen fixation, a six-electron/six-proton reduction process that produces NH₃ from N₂, is a

very crucial transformation, yet very challenging due to the inert nature of N₂.¹⁰ The homogeneous pincer complexes have demonstrated high activity for the same and representative examples have been discussed above, as it is beyond the scope of the current chapter to cover all the reports. The recent investigations have focused on use of various metals such as Ru, Os, V, Ti and Co and have explored their mechanism in comparison to Mo.¹⁰

1.1.1.4. Hydrofunctionalization of alcohols

1.1.1.4.1. Guerbet reaction

In the age of fast-depleting fossil fuels, alternative energy source are very necessary to satisfy the energy demand of the society.^{67, 68} Ethanol is acknowledged as a sustainable fuel, as it is very easy to access from fermentation process,⁶⁹ However, ethanol has poor energy density (70%)^{69, 70} and higher absorptivity towards water.⁷¹⁻⁷³ Therefore *n*-butanol is the alternative energy source because of its high energy density (85%) and its immiscibility with water.⁷¹⁻⁷³ Guerbet reaction is one such potential solution that can transform ethanol to *n*-butanol.⁷⁴ Since, the last decade, the pincer catalytic system has been widely employed for such transformation. Transition metal catalyzed dehydrogenation of ethanol produces the corresponding acetaldehyde, which in the presence of a base undergoes aldol-condensation to produce α , β unsaturated aldehyde with water as a sole by-product. Hydrogenation of this α , β unsaturated aldehyde produces the *n*-butanol (Scheme 1.11).

In 2016, Szymczak and co-workers developed (NNN) type pincer-ruthenium complex **1.Ru10** for Guerbet reaction of ethanol to *n*-butanol.⁷⁵ The catalyst **1.Ru10** (0.1 mol%) in presence of 5 mol% NaOEt and 0.4 mol% PPh₃ showed 53% conversion of ethanol towards *n*-butanol with 78% selectivity and 530 TON at 150 °C for 2 hours (Scheme 1.12). Under the same reaction conditions with only 0.001 mol% **1.Ru10** without 0.4 mol% PPh₃, 1.4% conversion of ethanol with 1.4% yield towards *n*-butanol was observed with 100% selectivity and 1400 TON (700 TOF).⁷⁵

In the same year Milstein carried out the Guerbet reaction with PNP and NNP type pincer-ruthenium complexes.⁷⁶ The **1.Ru1** (0.02 mol%) catalyzed the *n*-butanol formation from ethanol in the presence of 4 mol% NaOEt at 110 °C for 16 h to give 18.2% conversion (14.6 % yield, 86. 1% selectivity) and 18209 TON (Scheme 1.12).⁷⁶ When the reaction was carried out at elevated temperature (150 °C) for 40 hours in the presence of 20 mol% NaOEt and 0.02

mol% **1.Ru**, 73.4% conversion (35.8% yield, 31.8% selectivity) of ethanol towards *n*-butanol was observed with 3671 TON.⁷⁶

Scheme 1.11: Schematic representation of the transition metal catalyzed upgradation of ethanol to *n*-butanol.

In 2017, Liu and co-workers developed the PNP type pincer-manganese complexes for the conversion of ethanol to *n*-butanol.⁷⁷ The **1.Mn2** (0.00125 mmol) catalyzed the Guerbet reaction of ethanol (75 mL, 1275 mmol) in the presence of 12 mol% of NaOEt at 160 °C and after 7 days 11.2% conversion of ethanol with 9.8% yield of *n*-butanol with 92% selectivity and 114120 TON was observed (Scheme 1.12).⁷⁷ The Liu group reported the highest selectivity of 100% with 170 TON and 1.7% yield of *n*-butanol when the reaction was performed with **1.Mn2** (0.01 mmol), NaOAc (6 mol%) and EtOH (6 mL, 100 mmol) for 24 h at 160 °C.⁷⁷ They reported the highest yield of *n*-butanol of 22.7% with 87% selectivity and 286 TON using **1.Mn2** (0.1 mmol, 0.1 mol%), NaOEt (12 mol%) and EtOH (6 mL, 100 mmol) when the reaction was carried out at 160 °C for 96 h.⁷⁷

In a similar parallel investigation, Jones and co-workers reported the formation of *n*-butanol from ethanol using (PNP) type pincer-Mn complexes.⁷⁸ The catalyst **1.Mn2** (0.5 mol%) catalyzed the Guerbet reaction with 25 mol% of NaOEt at 150 °C for 24 h and 34% yield of *n*-butanol was obtained with 68 TON in presence of 1g molecular sieves (Scheme 1.12).⁷⁸

Recently, Kumar and co-workers developed a series of (NNN) type pincer-Ru complexes for the Guerbet reaction.^{68, 79a} The *bis*(imino)pyridine based pincer ruthenium complex $\text{Cy}^2(\text{NNN})\text{RuCl}_2(\text{CO})$ (**1.Ru11**) (0.05 mol%) in presence of 10% NaOEt provided 335 TON with 170 TOF (TOh^{-1}) and 90% selectivity at 140 °C for the *n*-butanol formation from ethanol (Scheme 1.13). Subsequently, the 2,6-*bis*(benzimidazole-2-yl)pyridine based pincer ruthenium complex ($\text{Bim}^2\text{NNN})\text{RuCl}_2(\text{CO})$ (**1.Ru12**) (0.025 mol%) in presence of 10% NaOEt provided

Scheme 1.12: Pincer-metal based homogeneous catalysts reported *n*-butanol formation from ethanol.

2100 TON with 710 TOF (TO h^{-1}) with 70% selectivity and 58% conversion at 140°C for longer time (72 h) for the *n*-butanol formation from ethanol (Scheme 1.13).^{79a} These pincer complexes are not only active under thermal conditions but also very active under microwave conditions. The 2,6-*bis*(benzimidazole-2-yl) pyridine based ruthenium pincer complex [$^{\text{Bim}2}\text{NNN}$)RuCl(PPh₃)₂]Cl (**1.Ru13**) catalyzed the *n*-butanol formation from ethanol in presence of 10 mol% NaOEt at 110°C under microwave irradiation at 75 W to obtain 8534 TO h^{-1} with 18% yield at 90% selectivity (Scheme 1.13). The 2,6-*bis*(benzimidazole-2-yl) pyridine based pincer ruthenium complex ($^{\text{Bim}2}\text{NNN}$)RuCl₂(CO) (**1.Ru12**) (0.025 mol%) in presence of 10% NaOEt provided 42% yield at 57% selectivity of *n*-butanol under microwave irradiation at 75 W at 110°C , whereas in same reaction conditions, at low loading of **1.Ru12** 0.00225 mol%, 13022 TON with 22.8% yield of *n*-butanol at 78% selectivity was observed (Scheme 1.13).

Scheme 1.13: Catalysts reported for *n*-butanol formation from ethanol by Kumar.^{68,79a}

The field of ethanol upgradation is very vast and there are some excellent reviews that provide a nice overview of the same.^{79b, c} The effort of this section is to just provide a glimpse of the utility of pincer complexes in this interesting chemistry.

1.1.1.4.2. β -alkylation of alcohols

Transition metal catalyzed dehydrogenation of primary and secondary alcohol produces the corresponding aldehyde and ketone, which in the presence of a base undergoes aldol condensation to produce α, β -unsaturated ketone with water as a sole by-product as observed in the Guerbet reaction. Hydrogenation of this α, β -unsaturated ketone produces the β -alkylated alcohol (Scheme 1.14).

Scheme 1.14: Schematic representation of C-alkylation using alcohol as a starting material.

In 2003, Shim and co-workers first demonstrated the β -alkylation of secondary alcohols with primary alcohols by using dichloro *tris*(triphenylphosphine)ruthenium(II) [RuCl₂(PPh₃)₃] in presence of NaOH. This methodology afforded a variety of β -alkylated alcohol products.⁸⁰ Later, Carbtree,^{81a} Yu,⁸² Achard,^{83a} Bera,⁸⁴ Kundu,^{85, 86} Ghosh,^{83b} Kumar,⁷⁹ Balaraman^{81b} and others have developed the β -alkylated alcohols or α -alkylated ketones from the condensation of secondary alcohols/ketones with primary alcohols using pincer-metal complexes. Moreover, the cross coupling of the secondary alcohols to generate the ketones has also been described by Gunanathan in two independent reports using **1.Ru18b**.^{83c,d}

Kundu and co-workers synthesized a series of pincer-ruthenium complexes and employed them for the β -alkylation of secondary alcohols with primary alcohols. The catalyst **1.Ru14** performed β -alkylation with 190 TON (Scheme 1.15).⁸⁶ The (NNN) based pincer-ruthenium catalyst **1.Ru16** showed metal ligand co-operativity and provided 31500 TON with 640 TO h⁻¹

¹ for the β -alkylation of secondary alcohols with primary alcohols (Scheme 1.15).⁸⁷ The N-hetero cyclic carbene (NHC) based on NNC-pincer-ruthenium catalyst **1.Ru15** with very low loading exhibited very good TON of 288000 (TOF 24000 h⁻¹) for β -alkylation reaction

Scheme 1.15: The homogeneous catalysts reported for β -alkylation of secondary alcohols with primary alcohols.^{79, 81-83, 85, 86}

(Scheme 1.15). The reaction was carried out under solvent free condition and the optimized catalytic protocol was found to be efficient for a large variety of substrates.

In 2017, Achard group synthesized NPN tridentate pyridine based ruthenium complex (**1.Ru18**) (Scheme 1.15) for the C-alkylation of secondary alcohols with primary alcohols but

formation of α -alkylated ketones was observed as a major product instead of β -alkylated alcohol.^{83a}

Bera group discovered the β -alkylation of secondary alcohols with primary alcohols using a *N*-heterocyclic carbene based iridium catalyst **1.Ir31a**. Due to the pyridyl(benzamide)-functionalized NHC backbone, the catalytic system demonstrated very good activity towards the β -alkylation with 1800 TON (Scheme 1.15).⁸⁴

In 2018, Yu and co-workers first reported Mn-catalyzed β -alkylation of secondary alcohols with primary alcohols. They have reported a series of pyridyl-supported pyrazolyl-imidazolyl ligand-based Mn(I) complexes for β -alkylation.⁸⁸ The complex **1.Mn3** among all the complexes showed highest activity for β -alkylation of secondary alcohols with primary alcohols. The **1.Mn3** (2.1 mol%) catalyzed the β -alkylation in presence of 30 mol% of KO^tBu at 110 °C for 24 h in N₂ atmosphere and 92 % β -alkylated product was obtained in alkylation of secondary alcohols with primary alcohols (Scheme 1.16). Using the optimized methodology, a large library of substrates were tested. Additionally, this protocol was extended for β -alkylation of cholesterol and its derivatives and one pot synthesis of flavan derivatives.⁸⁸

Scheme 1.16: The **1.Mn3** catalyzed β -alkylation of secondary alcohols with primary alcohols.⁸²

In 2021, Ghosh group developed an amido-functionalized ruthenium carbene complexes for

the β -alkylation of secondary alcohols with primary alcohols. The **1.Ru18a** (1 mol%) catalyzed the β -alkylation in presence of 1 equivalent of NaO^tPr at 110 °C after 3 hours to yield 72% of β -alkylated alcohol starting from benzyl alcohol and 1-phenylethanol as model substrates (Scheme 1.17).^{83b} The cationic picolyl functionalized NHC ruthenium complex also showed similar reactivity for the β -alkylation of secondary alcohols with primary alcohols. The hydride intermediate of **1.Ru18a** was detected and remained active for 120 h. A variety of substrates scope was carried out with good to moderate yield.

Gunanathan and co-workers used Ru-MACHO **1.Ru18b** for the catalytic cross coupling of secondary alcohols to get ketone product **1.4'**. The **1.Ru18b** (1 mol%) catalyzed the cross coupling of secondary alcohols in presence of 5 mol% of KO^tBu at 125 °C in toluene medium for 4 h to obtain selectively the crossed coupled ketone product **1.4'** (Scheme 1.18).^{83c} A variety of substrates with different functional groups could be used to achieve the selective formation of ketones.

Scheme 1.17: Ruthenium-carbene catalyzed β -alkylation of secondary alcohols with primary alcohols.^{83b}

The β -alkylation reaction is an excellent choice for the synthesis of C-C bonds, because it generates minimal amount of waste and requires only small amount of additives. This method has wide synthetic utility and leads to the production of valuable fine chemicals, fuel, agrochemicals and natural products.⁸² In pharmaceutical industry, β -alkylation finds utility in the preparation of Ezetimite (which reduces the amount of cholesterol absorbed),⁸² while in

cosmetics, this reaction is employed for the synthesis of Licochalcone A.⁸² The homogeneous pincer complexes based on precious metal salts are highly active for β -alkylation and have enjoyed a huge application. Some of the representative examples have been discussed here for

Scheme 1.18: Ruthenium catalyzed selective cross coupling of secondary alcohols.^{83c}

the basic understanding of β -alkylation.^{83e} The use of pincer complexes based on $3d$ metals is currently being explored for β -alkylation, however a detailed understanding of β -alkylation of secondary alcohols with primary alcohols has been discussed in Chapter-IV.

1.1.1.4.3. *N*-alkylation of alcohols

N-alkylated amines are versatile intermediates for organic transformation and also it has wide utility in dyes, polymers, pharmaceutical products and in the synthesis of fine chemicals.⁸⁹ Traditional methods involves the reaction of environmentally toxic alkyl halide with amines to produce *N*-alkylated amines.⁹⁰ Instead of using hazardous alkyl halide molecules, use of less hazardous alcohol molecules (precursor of alkyl halide) is more greener and atom economical for the transformation of amines and alcohols to *N*-alkylated amines.⁹¹ The transition metal complex catalyzes the *N*-alkylation in presence of stoichiometric amounts of base. Transition metal complex catalyzed dehydrogenation of primary alcohol produces the corresponding aldehyde which reacts with amine and produces imine with water as a sole by-product.⁹² Subsequent hydrogenation of imine produces the desired alkylated amine. (Scheme 1.19).⁹³⁻⁹⁶

The stoichiometric amounts of base or molecular sieves are used in *N*-alkylation to scavenge the by-product water which is formed in the reaction mixture.⁹² The *N*-alkylation reaction has been well-explored by Meilstein⁹³ Kirchner⁹⁴ Kundu⁹⁵ Kumar^{96a} and others. This reaction

proceeds *via* “hydrogen borrowing” strategy which involves transfer hydrogenation to mitigate the need of hydrogen gas, making it an overall atom efficient process (Scheme 1.19).

In 2016, Kirchner developed PNP pincer-Fe complexes and tested them for the *N*-Alkylation

Scheme 1.19: Schematic representation of *N*-alkylation using alcohol and amine as a starting material, with representative examples of well-explored catalytic systems.

reaction of amines and alcohols.⁹⁴ The **1.Fe6** (2 mol%) catalyzed the *N*-alkylation reaction of alcohol and amine in presence of 1.3 equivalents of KO^tBu in toluene medium (4 mL) at 80 °C for 16 hours. A large variety of substrates were *N*-alkylated with good to moderate yields (Scheme 1.20)⁹⁴ using the developed catalytic protocol.

In 2019, Kumar and co-workers developed a series of *bis*(imino)pyridine based pincer-Ru complexes and tested for *N*-alkylation reaction of amines and alcohols.⁹⁶ Pincer-ruthenium complexes of the type (R²NNN)RuCl₂(PPh₃) (**1.Ru19**; R = ^tBu, **1.Ru20**; R = ⁱPr **1.Ru21**; R = Cy, **1.Ru22**; R = Ph) have been used to accomplish *N*-alkylation of primary amines. For the first time, they reported the use of Na to generate the base *in-situ*, that made the reaction more favourable. The alcohol precursor was regenerated from sodium alkoxide by its reaction with water produced during the process. Thus, water formed in the reaction mixture enhanced the

rate of the catalytic cycle, making it more atom economical. The catalyst (^tBu₂NNN)RuCl₂(PPh₃) (**1.Ru19**) displayed highest TON of 29000 for *N*-alkylation of amine in solvent-free condition (Scheme 1.21).^{96a}

The *N*-alkylation reaction has huge application in industry, specially in pharmaceutical^{96b} and in medical chemistry.^{96b} The *N*-alkylated amines are used to prepare various drug molecules like Sertraline,^{96b} (effective antidepressant of various etiologies), Pramipexole, (agonist dopamine receptor and effective for Parkinson disease), Donepezil, (cholinesterase inhibitor) and Retigabine (used to normalize the potassium channel in neurons of the brain).^{96b} The *N*-alkylation of amines has been explored using various complexes and specially pincer complexes have exhibited higher efficiency for the selective formation of higher amines instead of imines.⁹⁴ This section has attempted to shed light on some of the efficient amines *N*-

alkylation catalysts as representative examples.

1.1.1.4.4. Catalytic β -methylation of various alcohols

Methylation is a very useful technique among various C–C bond formation reactions, where access to branching provided by methyl groups is highly important as a structural motif in chemistry and biology,⁹⁷ ranging from synthetic lubricants⁹⁸ to drug molecules.⁹⁹ The dehydrogenation of methanol is very challenging though methylation reactions are attractive towards alkylation. The dehydrogenation of methanol is highly challenging due to its high enthalpy ($\Delta H = 84$ kJ/mol). This highlights the importance to design and develop efficient catalysts and optimal catalytic methods for dehydrogenative functionalization using methanol as the alkylating agent.¹⁰⁰⁻¹⁰² Transition metal catalyzed dehydrogenation of methanol and 2-phenylethanol produces the corresponding aldehydes which in the presence of a base undergoes aldol-condensation to produce α , β -unsaturated aldehyde with water as a sole by-product. Hydrogenation of this α , β -unsaturated aldehyde produces the β -methylated alcohol (Scheme 1.22). A similar path for 1-phenylethanol can also be proposed (Scheme 1.22).

In 2014, Beller and co-workers reported the β -methylation of 2-phenylethanol (**1.7**) with a dual catalytic system Ru-MACHO (**1.Ru24**) (0.1 mol %) and Shvo's catalyst (**1.Ru23**) (0.05 mol %) that has resulted in 87% yield of **1.9** at 140 °C (Scheme 1.23).¹⁰³

Scheme 1.22: A general schematic representation of the transition metal catalyzed β -methylation of 2-phenylethanol.

In 2019, Leitner and co-workers reported a Ru-MACHO-BH₄ (**1.Ru25**) (0.1 mol%) catalyzed β -methylation of 2-phenylethanol and 1-phenylethanol with 2 equivalents of NaOMe at 150 °C for 28 h to obtain 82% of 2-phenylpropan-1-ol and 84% 2-methyl-1-phenylpropan-1-ol respectively (Schemes 1.24 and 1.25).¹⁰⁴ The complex **1.Ru25** showed excellent catalytic

activity with 18000 TON for the β -methylation of alcohol. A variety of substrates based on both 2-phenylethanol and 1-phenylethanol were tested and good to moderate yields were observed.¹⁰⁴

The β -methylation of alcohols has been explored independently by Renaud,¹⁰⁵ Kempe,¹⁰⁶ Leitner,^{104, 107, 108} Srimani,¹⁰⁹ Kundu,¹¹⁰ Morril^{102, 111} and others using homogeneous complexes based on Fe, Mn, Ru. The selected pincer-metal complexes for β -methylation of alcohols have been shown in Scheme 1.23. The activation of methanol molecule is challenging but very useful for various C–C bond formation reactions. The synthesis of new carbon-methyl bond as a structural motif is very important in chemistry, biology,⁹⁷ and it is used in applications ranging from lubricants⁹⁸ to drug molecules.⁹⁹ The β -methylation of alcohols is challenging yet various homogeneous

Scheme 1.23: Homogeneous pincer complexes reported for β -methylation of 2-phenylethanol and 1-phenylethanol.

pincer-metal complexes based on precious metals have been extensively reported that catalyze the β -methylation reaction effortlessly.¹⁰⁰⁻¹⁰² Here, some of the selected representative homogenous pincer-metal complexes have been discussed for β -methylation. The detailed reaction mechanism and other reports have been elaborately discussed in chapter-II. When the same reaction was carried out in the absence of methanol, the dehydrogenation product of 2-phenylethanol underwent self-coupling and produced alkane directly through decarboxylation coupling. There are very limited reports on decarboxylation of alcohol to alkane, therefore a detailed description is covered in chapter-III.

Scheme 1.24: The β -methylation of 2-phenylethanol and its derivatives catalyzed by **1.Ru28** catalyst.¹⁰⁴

Scheme 1.25: The β -methylation of 1-phenylethanol and its derivatives catalyzed by **1.Ru25** catalyst.¹⁰⁴

1.1.1.4.5. Alcohol reforming reaction: H₂ production

Hydrogen is regarded as one of the most efficient alternatives to non-renewable fuels.¹¹² In the of age of rapid depletion of fossil fuels, scientists are interested in the development of fuels based on renewable resources. Hydrogen is regarded as a clean fuel and an efficient energy carrier (120 MJ/Kg) that can be turned into electricity by utilising various fuel cell technologies

to get significant amount of energy per unit mass.¹¹³⁻¹¹⁵ The use of hydrogen will extend the range of available energy sources and recently there is significant progress in the field of hydrogen generation using liquid organic hydrogen carrier (LOHC) systems due their high hydrogen storage capacity, easy transportation and environmental friendliness.¹¹² Recently, particular emphasis has been laid on alcohols as LOHCs to generate on-demand hydrogen.¹¹² Many potential LOHC candidates for hydrogen storage include methanol, ethanol, ethylene glycol, glycerol etc., which lead to the production of various value-added chemicals along with the concomitant generation of hydrogen.¹¹² However, this section will focus on the hydrogen generation from methanol as a representative example. For alcohol reforming, methanol has a high hydrogen storage capacity (12.6 wt%) and is therefore considered a promising candidate for H₂ generation.¹¹⁶⁻¹¹⁹ Among the various alcohols, majority of the reports are based on aqueous reforming of methanol,¹¹² because of its easy availability. The reports with ethanol reforming are scarce due to the various side products formed during the reaction,^{112, 76-78} thereby affecting the selectivity of the process. In case of ethylene glycol, it has only 6.5 wt% H₂ and a higher boiling point, which makes it less favourable to produce hydrogen under mild conditions.¹¹² Therefore, methanol is the most preferred candidate for the catalytic aqueous reforming employing homogeneous catalysts under mild conditions.¹²⁰

Scheme 1.26: Schematic representation of aqueous MeOH reforming reaction.

Depending upon reaction conditions, methanol can be converted to different products like HCHO, HCOOH, CO₂, CO and H₂ (Scheme 1.26). For the on-site hydrogen generation, aqueous methanol-reforming is an attractive method as it involves the complete dehydrogenation of methanol into CO₂ and H₂.^{112, 121} A variety of homogeneous transition metal complexes can catalyze the aqueous reforming of methanol to H₂ (Scheme 1.27).^{112, 121}

In 2013, Beller and co-workers reported the use of pincer-ruthenium complexes based on the MACHO ligand to catalyze MeOH/H₂O mixture to CO₂ (or CO₃²⁻) and H₂.¹²¹ The pincer-ruthenium complexes (**1.Ru23** and **1.Ru28**) (21 ppm) in presence of 0.5 M base dehydrogenated a 4:1 methanol-water mixture to formaldehyde. In presence of base and water it gets further dehydrogenated to formic acid and at last to CO₂ and H₂ (3 equivalents) (Scheme 1.28). The complex **1.Ru23** and **1.Ru28** showed very good catalytic activity for the

Scheme 1.27: Complexes reported for aqueous MeOH reforming reaction.

reforming of methanol to hydrogen (Scheme 1.28).¹²⁰ The **1.Ru23** (1.8 ppm, 0.008 mol%) with 8.0 M KOH (1.4 equivalents with respect to water) gave 8.23% yield of H₂ with 1051 TOF (h⁻¹). On the other hand, under similar reaction conditions the catalyst **1.Ru28** showed better activity towards dehydrogenation of 9:1 MeOH/H₂O with 16.6% yield of H₂ at 2678 h⁻¹ after 3h at 91 °C. In neat methanol, after 3 hours an amazing TOF of 4734 h⁻¹ was observed with 9.1 % yield of hydrogen under similar reaction conditions,¹⁰⁶ while using catalyst **1.Ru28**. The

Scheme 1.28: **1.Ru23** and **1.Ru28** catalyzed aqueous reforming of methanol.¹⁰⁶

studies by Beller laid the foundation for the systematic development on the MeOH reforming reaction with different complexes. Milstein,^{122, 123} Beller,¹²⁴⁻¹²⁶ Kumar,¹²⁷ Hazari¹²⁸ and others developed various efficient homogeneous pincer-catalytic systems for aqueous phase methanol reforming reaction (Scheme 1.27).

LOHC have many potential applications that involves the storage and transportation of hydrogen by eliminating the need of cooling or compressing H₂ in an energy intensive manner.¹¹² This makes the handling of hydrogen not only safer but cheaper as well. The hydrogen generated can be utilized in various applications such as fuel cell, power generation, hydrogen refuelling station, transportation and industrial sectors.¹¹² Hence, it is pivotal to expand the on-site production of hydrogen from LOHC in order to fulfil its ever-increasing demand as a fuel. In this context, this section has provided a brief overview of the application of pincer complexes towards H₂ generation from abundant alcohols.

1.2. Summary

The concept of pincer-metal complexes, emerged in 1976, introduced by Moulton and Shaw, marks a significant milestone in the field of catalysis that has continued to evolve over past five decades. These versatile complexes have been widely applied across various fields, particularly in catalysis where they have played a transformative role. Numerous pioneering reports are there in this field that has demonstrated the effectiveness of these pincer metal complexes. These complexes have showcased outstanding catalytic properties in

fundamentally important dehydrogenation and hydrogenation reactions such as C-alkylation,^{79a, 81-86} N-alkylation,⁹³⁻⁹⁶ alkane dehydrogenation,^{7, 8} transformation of CO₂ to methanol⁹ and nitrogen fixation¹⁰ as well. Each of these areas have witnessed a significant growth, showcasing the wide utility of these complexes. While an in-depth discussion on each of the field is currently out of the scope of this thesis, we aim to provide a concise overview that highlights the most relevant reaction with representative example of these complexes. A detailed discussion on the literature for the relevant reactions has been provided in greater detail in the appropriate chapters. However, a significant amount of research is still ongoing globally that continues to lay emphasis on each of these reactions independently. All the observation presented above lay a solid foundation for the objectives of the current thesis.

1.3. Objective of the current thesis

The wide literature survey in this chapter discusses the role of pincer-metal complexes in various organic transformation that include the synthesis of fine chemicals, fuels, pharmaceuticals, and agrochemicals and, also the intermediates of various organic reactions. For a healthy global economy, energy self-sufficiency is essential. To satisfy the needs of energy of the society it is important to generate fine chemicals, fuel from abundant and cheap raw materials in an economical and environmentally-friendly fashion. The organometallic complexes with variety of metal-ligand combination under various optimized conditions have been successfully addressing the task to some extent. However, the expensive catalyst and sensitive reaction conditions are challenges that need to be addressed in the coming future. It would be beneficial if one could carry-out such transformation using an optimized reduced toxicity, low cost and less sensitive catalytic system. This thesis as a part of doctoral studies attempts to address the following questions,

1. Can we generate easy to synthesize *bis*(iminopyridine) based ligands instead of phosphine-based ligands and their corresponding pincer-ruthenium complexes?
2. Can we use these pincer-ruthenium catalysts to generate alkanes from alcohols *via* the challenging decarboxylative coupling?
3. Is it possible to use the simplest alcohol such as methanol as an alkylating agent in these pincer ruthenium catalysed reactions?
4. Can we substitute the ruthenium in these pincers catalytic systems with base metals such as cobalt and still obtain good activity in the C-C bond formation reactions using abundantly

available alcohols as alkylating agents?

Chapter- II

Pincer-Ru Catalyzed β -Methylation of Alcohols

The contents of this chapter have been adapted from “*Pincer-Ru Catalyzed β -Methylation of Alcohols*” by Nandi, P. G.; Jasra, R. V.; Kumar, A. *Organometallics* **2023**, 42, 3138-3152.

2.1 Introduction

The formation of C–C bonds serves as one of the key processes in the synthesis of natural products,¹ fine chemicals,¹ fuels,¹ pharmaceuticals,¹ and agrochemicals.¹ Conventionally, these C–C bond-forming reactions are accomplished via transition-metal-catalyzed activation of C–X (X = Cl, Br, I) bonds that typically involve organometallic² or radical pathways.³ In a bid to move away from stoichiometric hazardous waste generation,² global research has recently intensified its focus on the use of readily available alcohols as potential alkylating agents for the generation of versatile C–C bonds. Such alcohol refunctionalization reactions are known to proceed via the hydrogen auto-transfer⁴ or hydrogen-borrowing⁵ pathways, which have garnered greater research interest worldwide due to their green and atom economical nature with water as the only by-product.

Among various C–C bond formation reactions, methylation is a very useful tool where access to branching provided by methyl groups is highly important as a structural motif in chemistry and biology,⁶ ranging from drug molecules⁷ to synthetic lubricants.⁸ Though methylation reactions are attractive, the use of methanol as an alkylating agent requires one to accomplish the challenging dehydrogenation of methanol, which has a very high enthalpy ($\Delta H = 84$ kJ/mol). This underlines the importance of the need to design and develop efficient catalysts and catalytic methods for dehydrogenative functionalization using methanol as the alkylating agent.⁹

Transition metal catalyzed dehydrogenation of methanol and 2-phenylethanol produces the corresponding aldehydes which in the presence of a base undergoes aldol-condensation to produce α , β -unsaturated aldehyde with water as a sole by-product. Hydrogenation of this α , β -unsaturated aldehyde produces the β -methylated alcohol (Scheme 2.1). A similar path for 1-phenylethanol can also be proposed (Scheme 2.2).

Scheme 2.1: A general schematic representation of the transition metal catalyzed β -methylation of 2-phenylethanol.

Scheme 2.2: A general schematic representation of the transition metal catalyzed β -methylation reaction of 1-phenylethanol.

Among the catalysts that are known for the dehydrogenative functionalization, such as α - and β -alkylation of secondary alcohols using aliphatic primary alcohols as alkylating agents, catalysts based on Rh,^{10c} Ru,^{10a,f,j} and Ir^{10d,i} have enjoyed great success.¹⁰ However, for the methylation of alcohols at the sp^3 carbon, only a few catalytic systems have been reported.¹¹

Recently the β -methylation reaction has been explored independently by Tu,¹² Beller,^{11c} Renaud,^{13c} Kempe,⁴ Leitner,^{13a,14} and Morril,^{9b,13b} using homogeneous complexes^{4,9b,13} based on either Fe(0) or Mn(I). Apart from these few attempts to accomplish the β -methylation using catalysts based on earth-abundant 3d metals, there has been an equal emphasis toward identification of Ru-based β -methylation catalytic systems.

In 2019, Leitner and co-workers reported β -methylation of primary and secondary alcohols catalyzed by a borane adduct of the Ru–dihydrido complex [RuH(CO)(BH₄)(HN(C₂H₄PPh₂)₂)] (abbreviated as Ru-MACHO-BH) (**2.10Ru3**).^{11a,14} The Guerbet-type coupling of methanol with ethanol leading to isobutanol was reported by Wass using [RuCl₂(L)₂] (L = *bis*(diphenylphosphino)methane) as a catalyst.¹⁵ Recently Srimani reported a maximum yield of 90% in the methylation of 2-phenylethanol (**2.1**) catalyzed by 2 mol % (SNS)Ru(II) (**2.10Ru4**) after 36 h at 135 °C.¹⁶ The Kundu group have studied the methylation of both 2-phenylethanol (**2.1**) and 1-phenylethanol (**2.2**) resulting in up to 95% yield and 90% yield of **2.3** and **2.5**, respectively, in the reaction catalyzed by (NNC)Ru(II) (0.5 mol %) in the presence of Cs₂CO₃ (1 equivalent) at 140 °C for 24 h.¹⁷

Leitner and co-workers reported the highly selective β -methylation of alcohols using an earth-abundant first-row transition metal complex [Mn(CO)₂Br(HN(C₂H₄PⁱPr₂)₂)] **2.10Mn1**

Scheme 2.3: β -methylation reaction of 2-phenylethanol (**2.1**) and its derivatives by the Mn(I) catalyst **2.10Mn1**.^{13a}

((HN(C₂H₄P^{*i*}Pr₂)₂) = MACHO-^{*i*}Pr).^{13a} The best yield 94% of 2-(*p*-tolyl)propan-1-ol was obtained at 0.5 mol% loading of **2.10Mn1** in the presence of 2 equivalents of NaOMe at 150 °C after 24h in 1 mL methanol (Scheme 2.3). Alternatively, at a high loading of NaOMe (4 equivalents), double methylation of 1-phenylethanol (**2.2**) was achieved with 77% yield of 2-methyl-1-phenylpropan-1-ol (**2.5**) (Scheme 2.4). Excellent activity of the catalyst **2.10Mn1** was observed in the case of methylation of 2-phenylethanol. However moderate to good activity was observed for the **2.10Mn1** catalyzed methylation of 1-phenylethanol and its derivatives.^{13a}

Scheme 2.4: The β -methylation of 1-phenylethanol (**2.2**) and its derivatives catalyzed by Mn(I) catalyst **2.10Mn1**.^{13a}

In 2020, Kempe and co-workers reported the earth abundant metal catalyzed double and single methylation of 2-phenyl ethanol and 1-phenyl ethanol.⁴ The highest catalytic activity was observed with **2.10Mn2**. The best yield of 89% 2-methyl-1-phenylpropan-1-ol was obtained in the presence of 1.5 equivalents KO^tBu, at a loading of 0.1 mol% **2.10Mn2** and 3 equivalents methanol in 2 mL diglyme after 3h at 140 °C. A large number of substrates could be methylated using this protocol (Scheme 2.5).⁴

Scheme 2.5: The β -methylation of 1-phenylethanol (**2.2**) and its derivatives catalyzed by Mn(I) catalyst **2.10Mn2**⁴

Scheme 2.6: The β -methylation of 2-phenylethanol (**2.2**) and its derivative catalyzed by **2.10Fe1**.^{13c}

In 2019 Renaud and co-workers carried out the β -methylation of 2-phenylethanol in the presence of 2 mol% **2.10Fe1**, NaOH (10 mol%), ^tBuOH (1 mL) and NaO^tBu (1 equivalent) at 150 °C for 40h to get 71% of 2-methyl-1-phenylpropan-1-ol (**2.2a**) (Scheme 2.6). Notably the catalyst is moderately active for other 2-phenylethanol substrates.^{13c}

Scheme 2.7: The β -methylation of 2-phenylethanol and its derivatives catalysed by **2.10Ir1** catalyst.¹²

Scheme 2.8: The β -methylation of 1-phenylethanol and its derivatives catalyzed by **2.10Ir1** catalyst.¹²

Tu and co-workers carried out the methylation reaction using *bis*-N-heterocyclic carbene based iridium (*bis*-NHC-Ir) complex at a low catalyst loading, broad substrates scope was achieved with excellent yields (Scheme 2.7 and Scheme 2.8). They carried out the β -methylation of 2-phenylethanol catalyzed by *bis*-NHC Ir complex (**2.10Ir1**) (0.05 mol %) in the presence of 2 equivalents of NaO^tBu and obtained up to 99% yield at 140 °C.¹² DFT studies and other control experiments revealed that the ligand effect is critical for achieving an excellent catalytic activity towards the methylation of 2-phenylethanol and 1-phenylethanol.¹²

Beller and co-workers developed a catalytic system based on Ru-MACHO for the methylation of 2-phenyl ethanol under drastic condition (200 °C, 1.6 equivalents NaOMe) to achieve sufficient conversion. However co-operativity of two ruthenium complexes namely **2.10Ru1** (Shvo catalyst) and **2.10Ru2** (Ru-MACHO) is a key to success for the methylation of 2-aryl ethanols.^{11c} The dual catalytic system based on Ru-MACHO (0.1 mol %) (**2.10Ru2**) in conjug-

Figure 2.1. Homogeneous ruthenium catalysts reported for the β -methylation of 2-phenylethanol (**2.1**) and 1-phenylethanol (**2.2**).

Scheme 2.9: The β -methylation of 1-phenylethanol and its derivatives catalyzed by **2.10Ru1** in the presence of **2.10Ru2** as co-catalyst.^{11c}

-ation with Shvo's catalyst (**2.10Ru1**) (0.05 mol %) (Figure 2.1) for the β -methylation of 2-phenylethanol (**2.1**) that resulted in up to 87% yield of **2.3** at 140 °C.^{11c} Using these co-catalysts a large library of substrates were transformed to corresponding products with moderate to good yields (Scheme 2.9, Figure 2.1).

Scheme 2.10: The β -methylation reaction of 1-phenylethanol and its derivatives catalyzed by **2.10Ru5**.¹⁷

Recently Kundu and co-workers developed (NNC)Ru(II) pincer complexes which show very good activity for the β -methylation reaction for wide range of substrates (Scheme 2.10, Figure 2.1).¹⁷

2.2. Objectives of the current work

A comprehensive literature survey reveals that the pincer complexes are very much active for the activation of alcohols molecules. Our recent success in the synthesis of a series of NNN pincer-ruthenium complexes (**2.6a–d** and **2.10a–b**; Figure 2.2) based on *bis(imino)pyridine* and *2,6-bis(benzimidazol-2-yl)-pyridine* ligands for accomplishing catalytic reactions like N-alkylation,¹⁸ glycerol transformation to lactic acid,¹⁹ β -alkylation,²⁰ methanol reforming,^{21a} ethanol reforming,^{21b} and Guerbet reactions^{20,22a} prompted us to test these catalysts for potential β -methylation reactions that involve dehydrogenation as a key step in the presence of base. To the best of our knowledge there are no reports on the β -methylation reaction using *bis(imino)pyridine* and *2,6-bis(benzimidazol-2-yl)pyridine* based pincer complexes. On the basis of these facts, the current work attempts to address the following questions

- Can we utilize the pincer-Ru complexes based on *bis(imino)pyridine* and *2,6-bis(benzimidazol-2-yl)pyridine* ligands for the β -methylation of alcohols?
- Can we extrapolate the catalytic activity towards β -methylation of alcohols from Guerbet reaction?
- Are various functional groups tolerated?
- Can we get better activity with *bis(benzimidazol-2-yl)pyridine* ligand based pincer-Ru complexes instead of those based on *bis(imino)pyridine* ligand?

Figure 2.2. Pincer-ruthenium complexes investigated in the current study for the β -methylation of alcohols.

Gratifyingly, in this chapter, apart from the previously reported complexes, three new pincer-ruthenium complexes (**2.7**, **2.8**, and **2.9**; Figure 2.2) were synthesized and were employed towards the catalytic β -methylation reaction. After 24 h at 140 °C, we were able to obtain up to 92% yield of **2.3** in the methylation of 2-phenylethanol (**2.1**) catalyzed by **2.10b** (0.5 mol %) in the presence of 0.75 equivalents of KOH and up to 92% yield of dimethylated product **2.5** in the methylation of 1-phenylethanol (**2.2**) catalyzed by **2.10b** (0.5 mol %) in the presence of 2 equivalents of Na. Both protocols were used to efficiently accomplish the synthesis of several derivatives of **2.3** and **2.5**.

2.3. Results and discussion

2.3.1. Synthesis and characterization of pincer-ruthenium complexes 2.7–2.9 based on bis(imino)pyridine ligands

The NNN pincer-Ru phosphine complexes **2.7** and **2.8** containing the *p*-F and *p*-CF₃ groups were synthesized in good yields by treatment of the corresponding ligands^{2e,18–20,23} with RuCl₂(PPh₃)₃ under an argon atmosphere at reflux for 12 h, and the NNN pincer-Ru phosphine complex **2.9** with a *p*-OMe moiety was synthesized in a similar fashion but at room temperature, followed by washing with diethyl ether and hexane (Scheme 2.11). Complexes **2.7–2.9** were fully characterized by HRMS, ¹H NMR, ³¹P NMR, and ¹³C NMR studies. HRMS analysis of **2.7**, **2.8**, and **2.9** (Figures 2.S58–2.S66) demonstrated prominent peaks at *m/z* 720.0725, *m/z* 820.0675, and *m/z* 744.1131 that correspond to [2.7 – Cl]⁺, [2.8 – Cl]⁺ and [2.9

– Cl]⁺ respectively. The ³¹P NMR spectrum exhibited a single peak for each of the complexes **2.7** and **2.8** at $\delta = 31.90$ ppm and at $\delta = 30.74$ ppm. However, for **2.9** two peaks were observed at $\delta = 29.09$ ppm (minor amounts, ca 33% where PPh₃ is *trans* to pyridyl N) and at $\delta = 33.20$ ppm (major amounts, 67 %, PPh₃ *trans* to chloride).

Good quality crystals of **2.7**, **2.8**, and **2.9** were obtained for SCXRD analysis by slow evaporation of their solutions (10 mg each in 1 mL) from a methanol/hexane mixture, a methanol/DCM mixture, and DCM, respectively. Notably, **2.7**, **2.8**, and **2.9** crystallized in space groups *P21/c*, *Pna21*, and *P1̄*, respectively (Table 2.1 and 2.S1).

Scheme 2.11. General synthetic route to NNN pincer-ruthenium complexes^a

^aThe molecular structures of **2.8'**, **2.9'**, **2.7**, **2.8**, and **2.9** are provided as ORTEPs drawn at 50% probability. The phenyl groups on the P atoms and all of the hydrogen atoms in **2.7**, **2.8**, and **2.9** have been omitted for the sake of clarity.

2.3.2. Pincer-ruthenium-catalyzed methylation of 2-phenylethanol

The catalytic methylation reactions of 2-phenylethanol (**2.1**) as a model alcohol was initiated using 0.5 mol % (*i*Pr²NNN)RuCl₂(PPh₃) (**2.6a**) in the presence of various bases at 140 °C. In the presence of 19.2 equivalents of methanol at 140 °C, the yield of the **2.6a**-catalyzed methylation of **2.1** increased with an increase in the amount of NaOH used, giving methylated product **2.3** in a maximum yield of 54% (entries 1–5, Table 2.3). As the **2.6a** catalyzed methylation levelled off at a loading of NaOH higher than 0.75 equivalents (entry 3, Table 2.3), further optimization of the **2.6a**-catalyzed methylation of **2.1** was performed with 0.75 equivalents of NaOH at 140 °C. While increased loading of **2.6a** resulted in a marginal rise in the yield of **2.3** (entry 8, Table 2.3), at lower catalyst loadings there was a concomitant decrease in the yield of **2.3** (entries 6 and 7, Table 2.3).

Notably, no methylation of **2.1** was observed in the absence of the catalyst (entries 9 and 10, Table 2.3). The yield of the **2.6a** catalyzed methylation of **2.1** in the presence of 0.75 equivalents of NaOH was lower when the reaction was performed at 120 °C (entry 11, Table 2.3). Upon repeating the **2.6a**-catalyzed methylation of **2.1** under the optimized conditions (entry 3, Table 2.1), but with varying amounts of methanol (entries 12– 15, Table 2.3), the best results (ca. 76% yield of **3** after 24 h) were obtained with 7.5 equivalents of methanol (entry 14, Table 2.3) at 140 °C. Shortening the duration of the **2.6a**-catalyzed methylation of **2.1** using 7.5 equivalents of methanol in the presence of 0.75 equivalents of NaOH at 140 °C to 12 h lowered the yield of **2.3** (entry 16, Table 2.3). Under these new optimized conditions (entry 14, Table 2.3), good yields were obtained either by the use of KOH or by the use of Na (to generate the base *in-situ*)¹⁸ (entries 17 and 24, Table 2.3). While the yields of **2.3** were appreciable when KO^tBu and NaO^tBu were used (entries 18 and 21, Table 2.3), very poor yields were observed with the use of bases based on the carbonate and bicarbonate salts of potassium and sodium (entries 19, 20, 22, and 23, Table 2.3). Among the pincer–ruthenium catalysts **2.6–2.9** based on *bis*(imino)pyridine ligands, only **2.6a** provided good yields of methylated product **2.3** under the optimized conditions (entry 1 vs entries 2–7, Table 2.4). When the pincer–ruthenium catalysts **2.10a** and **2.10b** based on 2,6-*bis*(benzimidazol-2-yl)pyridine ligands were

^aReaction conditions, unless specified otherwise: 1 mmol of **2.1**, 7.5 mmol of MeOH, 0.75 equivalents of KOH, and 0.5 mol % Ru catalyst at 140 °C for 24 h in a 5 mL Schlenk flask under an argon atmosphere. ^bDetermined by ¹H NMR analysis using toluene as the standard. ^cAverage of two runs.

The generic nature of the **2.10b**-catalyzed synthetic protocol was demonstrated by applying it for the catalytic methylation of close to 18 derivatives of 2-phenylethanol (Table 2.5). In general, 2-phenylethanol derivatives with electron-donating and electron-withdrawing groups at the *para* position gave yields that were slightly lower than the corresponding yields obtained when 2-phenylethanol was used (**2.3a**, **2.3b**, **2.3k**, **2.3m**, and **2.3p** vs **2.3**, Table 2.5). While the 2-phenylethanol derivative with a *p*-nitro group was inactive toward methylation (**2.3n**, Table 2.5), the methylation of the corresponding *p*-bromo derivative resulted in debromination leading to a mixture of **2.3d** and **2.3** (Table 2.5).

The yields of methylated products obtained from the *meta*-substituted 2-phenylethanol derivatives (**2.3c**, **2.3f**, **2.3h**, and **2.3i**, Table 2.5) were comparable to the yield of **2.3**. On the other hand, *ortho*-substituted 2-phenylethanol derivatives and 2-thiopheneethanol performed very poorly (**2.3i**, **2.3j**, and **2.3e**) in the **2.10b** catalyzed methylation reaction, presumably due

to steric effects and deactivation via chelation, respectively. A moderate yield of **2.3o** was obtained in the methylation reaction of 1- naphthaleneethanol catalyzed by **2.10b** at 140 °C in the presence of 0.75 equivalents of KOH after 24 h (Table 2.5).

Efforts were then focused on optimizing a synthetic protocol for the methylation of 1-phenylethanol (**2.2**) using **2.10b** as a catalyst. Upon employing the conditions that gave the best

^aReaction conditions, unless specified otherwise: 1 mmol of **2.2**, 7.5–49.6 mmol of MeOH, Y equivalents of base, and X mol % Ru catalyst at 140 °C for 24 h in a 5 mL Schlenk flask under an argon atmosphere. ^bDetermined by ¹H NMR analyses using toluene as the standard.

results for the methylation of 2-phenylethanol (entry 9, Table 2.4), the **2.10b** (0.5 mol %)-catalyzed methylation of **2.2** at 140 °C in the presence of 0.75 equivalents of KOH for 24 h resulted in a mixture of monomethylated product **2.4** (48%) and demethylated product **2.5**

(30%) (entry 1, Table 2.6). Repeating the reaction with a higher amount of methanol (24.8 equivalents rather than 7.5 equivalents) resulted in dimethylated **2.5** as the major product (44%; entry 2, Table 2.6). Switching to use Na (to generate the base *in-situ*) resulted in higher selectivity toward **2.5** in the **2.10b** (0.5 mol %)-catalyzed methylation reaction of 1-phenylethanol at 140 °C (entries 3 and 4, Table 2.6). However, the reactivity (29% total yield) and selectivity dropped at very high dilutions in methanol (49.6 equivalents; entry 5, Table 2.6).

Considering 24.8 equivalents as an optimized methanol amount (entry 4, Table 2.6), the loading of Na was then increased to obtain **2.5** with a maximum yield and selectivity of about 92% (compare entry 8 with entries 6, 7, and 9, Table 2.6). At this optimized Na loading of 2 equivalents in the **2.10b** (0.5 mol %)-catalyzed methylation reaction of 1-phenylethanol at 140 °C using 24.8 equivalents of methanol, the yield and selectivity of **2.5** obtained upon using other bases such as NaOH, KOH, NaO^tBu, KO^tBu, Cs₂CO₃, Na₂CO₃, and K₂CO₃ were less as compared to the corresponding results obtained with Na (entry 8 vs entries 10–16, Table 2.6). The loading of 0.5 mol % **2.10b** was found to be optimal (entry 8 vs entries 19–21, Table 2.6), and **2.10b** clearly outperformed both **2.6a** and the precursor RuCl₂(PPh₃)₃ (entry 8 vs entries 17 and 18, Table 2.6).

The optimized catalytic system for the dimethylation of 1-phenylethanol was then applied for the screening of about 24 1-phenylethanol derivatives (Table 2.7). In general, good yields of dimethylated products were obtained in the **2.10b**-catalyzed dimethylation of 1-phenylethanol derivatives in the presence of 2 equiv of Na at 140 °C after 24 h using 24.8 equivalents of methanol (**2.5**, **2.5f**, **2.5g**, **2.5j**, **2.5l**, **2.5o**, **2.5q**, and **2.5r**, Table 2.7).

In stark contrast to the methylation of the *p*-bromo derivative of 2-phenylethanol, the corresponding demethylation of the *p*-bromo derivative of 1-phenylethanol did not result in debromination, and about 78% yield of dimethylated product **2.5a** was observed (Table 2.7). However, debromination leading to a mixture of **2.5h** and **2.5** was observed when the *m*-bromo derivative of 1-phenylethanol was used (Table 2.7). The **2.10b** catalyzed dimethylation of 1-(furan-2-yl)ethanol could be achieved in the presence of 2 equivalents of Na leading to the formation of **2.5c** in 64% yield at 140 °C after 24 h using 24.8 equivalents of methanol (Table 2.7). The performance of **2.10b** in accomplishing the dimethylation of 1-(pyridin-2-yl)ethanol was not appreciable and led to only a 20% yield of **2.5d**. The low reactivity of 1-(pyridin-2-yl)ethanol may be attributed to catalyst deactivation via chelation. In contrast, **2.10b** could

catalyze the dimethylation of 1-(pyridin-3-yl)ethanol and 1-(pyridin-4-yl)ethanol with moderate efficiency and resulted in 49% and 51% yields of **2.5m** and **2.5s**, respectively. The

Table 2.7. Methylation of various 1-phenylethanol derivatives catalyzed by 2.10b^a

^aReaction conditions, unless specified otherwise: 1 mmol of **2.2**, 24.8 mmol of MeOH, 2 mmol of Na, and 0.5 mol % **2.10b** at 140 °C for 24 h in a 5 mL Schlenk flask under an argon atmosphere. The yields were determined by ¹H NMR analyses using toluene as the standard. ^bAverage of two runs.

presence of $-\text{CF}_3$, $-\text{OCF}_3$, and $-\text{NO}_2$ groups at the *para* position resulted in lower yields of dimethylated products (**2.5b**, **2.5k** and **2.5p**, Table 2.7).

Figure 2.3. (a) Variation of the initial rate of formation of **2.3** with the concentration of **2.1**, reaction conditions: (0.25–1.00 mmol of **2.1**, 7.5 mmol of MeOH, 0.75 mmol of KOH, and 0.5 mol % **2.10b** at 140 °C for 24 h in a 5 mL Schlenk flask under an argon atmosphere). Also see Figures 2.S73–2.S76 and Figure 2.9 (b) Variation of the initial rate of formation of **2.3** with the concentration of **2.10b** (reaction conditions: 1 mmol of **2.1**, 7.5 mmol of MeOH, 0.75 mmol of KOH, and 0.1–0.5 mol % **2.10b** at 140 °C for 24 h in a 5 mL Schlenk flask under an argon atmosphere). Also see Figures 2.S76–2.S78 and Figure 2.10.

2.3.3. Control experiments

The ^1H NMR experiments performed during the current studies (Figures 2.5 and 2.S82) and the HRMS analysis along with the mercury-drop experiments previously reported by us^{21a} are indicative of the integrity of the pincer fragment and show that the imino groups are intact during catalysis. The bonding of the *bis*(imino)pyridine fragment in a meridional fashion to Ru imparts a very high stability to the resulting pincer. In addition, the steric encumbrance around the imino groups bound to the metal strongly disfavors any reactivity such as insertion into M–H bonds and σ -bond metathesis reactions. Hence, the destruction/ reduction of the imino groups of the pincer fragment is highly unlikely.

In the current studies, detailed mechanistic studies were performed with the most efficient catalyst **2.10b** based on the 2,6-*bis*(benzimidazol-2-yl)pyridine ligand. Kinetic experiments were carried out to determine the order of the **2.10b**-catalyzed methylation of **2.1** in the presence of 0.75 equivalents of KOH using 7.5 equivalents of methanol at 140 °C (Figure 2.3). Using the initial rate method, a first-order dependence of the rate was observed on the

concentrations of both **2.1** and **2.10b**, which points to the homogeneous nature of the reaction. Additional evidence for the homogeneous nature of the reaction involving well-defined

Figure 2.4. HRMS of the reaction mixture containing 2-phenylethanol (0.120 mL, 1 mmol), methanol (0.303 mL, 7.5 mmol), KOH (0.042 g, 0.75 mmol), and **2.10b** (5.16 mg, 5 μ mol) maintained at (a) room temperature ($t = 0$ h) and (b) 140 $^{\circ}$ C for 1 h. Also see Figures 2.S68–S72.

molecular catalysts was obtained from mercury poisoning experiments that led to hardly any change in reactivity (equation 9, Scheme 2.12). Analysis of the headspace of the reaction vessel of the **2.10b** catalyzed methylation of either **2.1** or **2.2** under the optimized conditions (entry 9, Table 2.4 and entry 8, Table 2.6) revealed the evolution of hydrogen (equation 1, 5 and 6, Scheme 2.12 and Figures 2.S79–2.S8 and 2.6-2.8). The involvement of formaldehyde during the reaction was confirmed by its independent experiment with 2-phenylethanol under the optimized conditions which led to the β -methylated product **2.3** (equation 2, Scheme 2.12). This validates the likely formation of formaldehyde as the dehydrogenation product of methanol (equation 6, Scheme 2.12).

Methylation of acetophenone (**2.2a**) under the optimized conditions led to formation of monomethylated product **2.4**, dimethylated product **2.5**, and hydrogenated product **2.2** in 10%, 88%, and 2% yield, respectively (equation 3, Scheme 2.12). This observation is indicative of

Scheme 2.12. Control experiments

the intermediacy of **2.2a** in the **2.10b** catalyzed methylation of **2.2**. Further, the intermediacy of **2.4** in the **2.10b**-catalyzed methylation of **2.2** was also confirmed by independently

performing its methylation under the optimized conditions, which gave rise to **2.5** in quantitative yield (equation 4, Scheme 2.12). Competitive deuterium labeling studies reveal a secondary kinetic isotope effect (KIE) of 1.56²¹ (equation 10, Scheme 2.12). It is hence unlikely that C–H activation is a part of the rate-determining step (RDS), though it is involved in the catalytic cycle. The productivity of the **2.10b**-catalyzed methylation of **2.1** was greatly affected by the presence of externally added PPh₃ (equation 7 and 8, Scheme 2.12), which highlights the importance of the dissociation of PPh₃ from the pincer–ruthenium complex in generating the catalytically active species (Scheme 2.13).

Scheme 2.13. Generation of catalytically active species **2.12a** via dissociation of PPh₃ from **2.10b** followed by salt metathesis.

2.3.4. Plausible mechanism involved in the **2.10b**-catalyzed methylation reaction

A catalytic cycle has been proposed employing the most efficient catalyst **2.10b** for the methylation of **2.1** as a model alcohol (Schemes 2.13–2.16). This catalytic cycle has also been probed computationally using the PBE method with the LANL2DZ basis set for metal atoms and the 6-311G(d,p) basis set for non-metal atoms (Schemes 2.14–2.16). The generation of 16-electron five-coordinate dichloride species **2.11** (Scheme 2.13) is likely to be the first step via the dissociation of the ancillary ligand (PPh₃ from **2.10b**). The loss of PPh₃ was detected as Ph₃PO both in the HRMS analysis (*m/z* 279.0935; Figure 2.4) and in the ³¹P NMR spectrum (δ = 31.37 ppm; Figure 2.5b,c) of the reaction catalyzed by **2.10b**. As the NMR spectrum and HRMS analysis were performed under air, the pincer–ruthenium is likely to have catalyzed the oxidation of the dissociated PPh₃ to PPh₃O. This observation is very common for Ru(II)-based catalysts under air.^{21a,22} The salt metathesis of 16-electron five-coordinate dichloride species

2.11 with KOR (R = Me or CH₂CH₂Ph) results in the formation of the active Ru–alkoxide species **2.12** (Scheme 2.13).¹⁹ Interestingly, only **2.12a** was detected not only in HRMS analysis (*m/z* 1032.2315; Figure 2.4) but also in NMR studies (³¹P: δ = 50.65 ppm; Figure 2.5b) as its phosphine adduct, which apparently points to it being one of the resting-state species.

Figure 2.5. (a) ³¹P NMR spectrum of **2.10b** in CDCl₃. (b) ³¹P NMR spectrum of the reaction mixture containing containing methanol (1 mL, 24.8 mmol), KOH (0.056 g, 1.0 mmol), and **2.10b** (10.35 mg, 0.01 mmol) maintained at room temperature (*t* = 0 h) under air. (c) ³¹P NMR spectrum of the reaction mixture containing methanol (1 mL, 24.8 mmol), KOH (0.056 g, 1.0 mmol), and **2.10b** (10.35 mg, 0.01 mmol) maintained at 140 °C for 5 min under air. The hydride region of the ¹H NMR spectrum is given in the inset.

The catalytic cycle begins with the β -hydride elimination from **2.12a/2.12b** via **TS-2.13a/TS-2.13b** to yield Ru–H species **2.14** along with the formation of carbonyl compound **2.1'** and/or formaldehyde (Scheme 2.14). Subsequent σ -bond metathesis of the O–H of methanol or **2.1** with the Ru–H bond in **2.14** regenerates **2.12a/2.12b** along with the production of hydrogen, going through **TS-2.15a/TS-2.15b** (Scheme 2.14). Interestingly, the Ru–H species **2.14** is detected as its phosphine adduct **2.14a** both in NMR (³¹P: δ = 49.08 ppm; ¹H: triplet at δ =

–4.47 ppm; Figure 2.5c) and HRMS analysis (m/z 966.2468; Figure 2.4b), indicating that it is a resting state of the reaction. This is well in agreement with the comparison of the energetics of the dehydrogenation of methanol and **2.1**, which reveals that the overall dehydrogenation of the former is more endergonic by 7.05 kcal/mol. Further, for both the dehydrogenation of methanol and **2.1**, the σ -bond metathesis (**2.14** \rightarrow **TS-2.15a/TS- 2.15b** \rightarrow **2.12a/2.12b**) is the rate-determining step, with the overall RDS lying in the dehydrogenation segment of the former ($\Delta G_{140}^\ddagger = 24.06$ kcal/mol) (Scheme 2.14).

The catalytic dehydrogenation cycle is followed by an uncatalyzed base-mediated condensation of formaldehyde with **2.1'** leading to the formation of **2.16**. The olefinic bond in **2.16** can insert into the Ru–H bond in **2.14** to yield **2.18** via **TS-2.17** (Scheme 2.15). This step can undergo σ -bond metathesis either with hydrogen is exergonic ($\Delta G_{140} = -7.05$ kcal/mol) with a barrier of 9.46 kcal/mol. The intermediate **2.18** (hydrogenolysis) or with the O–H bond of methanol/**2.1** (alcoholysis) to result in the regeneration of **2.14/2.12a/2.12b** along with the formation of **2.22**, going through **TS- 2.19/TS-2.20/TS-2.21** (Scheme 2.15). Apparently, the hydrogenolysis step is both thermodynamically ($\Delta\Delta G_{140} = -9.54$ kcal/mol with H_2 vs $\Delta\Delta G_{140} = -0.68$ kcal/mol with methanol and $\Delta\Delta G_{140} = 0.85$ kcal/mol kcal/mol with **2.1**) and kinetically ($\Delta G_{140}^\ddagger = 21.51$ kcal/ mol with H_2 vs $\Delta G_{140}^\ddagger = 23.12$ kcal/mol with methanol and $\Delta G_{140}^\ddagger = 24.97$ kcal/mol with **2.1**) favored in comparison with the alcoholysis step (Scheme 2.15).

In a similar fashion, insertion of a carbonyl group in **2.22** into the Ru–H bond of **2.14** followed by hydrogenolysis/alcoholysis would result in the formation of the product **2.3** via the path (**2.14** \rightarrow **TS-2.23** \rightarrow **2.24** \rightarrow **TS-2.25/TS-2.26/TS-2.27** \rightarrow **2.14/2.12a/2.12b**) (Scheme 2.16). The insertion of **2.22** into the Ru–H bond of **2.14** is endergonic ($\Delta G_{140} = 6.03$ kcal/mol) with a barrier of 18.25 kcal/mol (**TS-2.23**). We were not able to locate **TS-2.26** and **TS- 2.27** for the alcoholysis step (Figure 2.S83). However, while step **2.24** \rightarrow **2.12a** is endergonic ($\Delta\Delta G_{140} = 1.52$ kcal/mol), the corresponding step **2.24** \rightarrow **2.12b** is thermodynamically neutral ($\Delta\Delta G_{140} = 0.00$ kcal/mol). In comparison, the hydrogenolysis step **2.24** \rightarrow **2.14** is exergonic ($\Delta\Delta G_{140} = -8.87$ kcal/mol) with a barrier of 13.69 kcal/mol (**TS-2.25**). The thermodynamics of the alcoholysis step in this segment (Scheme 2.16) is very much comparable to that of the corresponding alcoholysis steps **2.18** \rightarrow **2.12a** ($\Delta\Delta G_{140} = -0.68$ kcal/mol) and **2.18** \rightarrow **2.12b** ($\Delta\Delta G_{140} = 0.85$ kcal/mol) in the previous segment (Scheme 2.15). Taking a cue from the previous step, one may infer that hydrogenolysis is the favored pathway in the overall transformation of **2.22** to **2.3**, which is exergonic ($\Delta G_{140} = -2.84$ kcal/mol) with a rate

determining hydrogenolysis barrier of 13.69 kcal/mol (Scheme 2.16).

A comparison of the individual RDSs of the segments related to the transformation of methanol/**2.1** → formaldehyde/**2.1'** (Scheme 2.14), **2.16** → **2.22** (Scheme 2.15) and **2.22** → **2.3** (Scheme 2.16) suggests that the overall RDS is the dehydrogenolysis step (**TS-2.15a**; $\Delta G_{140}^\ddagger = 24.06$ kcal/mol) that lies in the methanol → formaldehyde dehydrogenation segment (Scheme 2.14). This is in line with the observed secondary KIE of 1.56^{21b} (equation 9, Scheme 2.12). Not surprisingly, none of the intermediates involved in the cycles **2.1** → **2.1'** (Scheme 2.14), **2.16** → **2.22** (Scheme 2.15), and **2.22** → **2.3** (Scheme 2.16) are observed in the HRMS analysis. Furthermore, in the overall RDS **2.14** → **TS-2.15a** → **2.12a**, as **2.14** ($\Delta G_{140} = -1.18$ kcal/mol) has a lower energy than **2.12a** ($\Delta G_{140} = 9.21$ kcal/mol) (Scheme 2.14), its phosphine adduct **2.14a** is observed as the resting state, which was detected by both NMR (³¹P: $\delta = 49.08$ ppm; ¹H: triplet at $\delta = -4.47$ ppm; Figure 2.5c) and HRMS analysis (*m/z* 966.2468; Figure 2.4b). The comparable energies of **2.14** ($\Delta G_{140} = -1.18$ kcal/mol) and **2.12** ($\Delta G_{140} = 0.00$ kcal/mol) mean that the step **2.12a** → **TS-2.13** → **2.14** may be reversible, and not surprisingly, **2.12a** is also the resting state, as it was detected in the HRMS analysis (*m/z* 1032.2315; Figure 2.4) and NMR studies (³¹P: $\delta = 50.65$ ppm; Figure 2.5b) as its phosphine adduct.

Figure 2.6: Evidence for the evolution H₂ in dehydrogenation of methanol catalyzed by **2.10b** (0.5 mol %) at 140 °C via GC analysis.

Figure 2.7: Evidence for the evolution H₂ in dehydrogenation of 2-phenyl ethanol (**2.1**) and methanol catalyzed by **2.10b** (0.5 mol %) at 140 °C via GC analysis.

Figure 2.8: Evidence for the evolution H₂ in dehydrogenation of 1-phenyl ethanol (**2.2**) and methanol catalyzed by **2.10b** (0.5 mol %) at 140 °C via GC analysis.

2.4. Conclusion

We have reported the synthesis and characterization of three NNN pincer–ruthenium complexes based on *bis*(imino)-pyridine ligands. The β -methylation of 2-phenylethanol and selective β -dimethylation of 1-phenylethanol using methanol as an alkylating agent have been accomplished using pincer–ruthenium catalysts based on *bis*(imino)pyridine and 2,6-*bis*(benzimidazol-2-yl)pyridine ligands. Among the considered catalysts, the pincer–ruthenium complex $[(^{\text{MeBim2}}\text{NNN})\text{RuCl}(\text{PPh}_3)_2]\text{Cl}$ based on the dimethyl-substituted 2,6-*bis*(benzimidazol-2-yl)pyridine ligand was found to be the most efficient. In particular, up to 92% yield of β -methylated 2-phenylethanol was obtained at 140 °C in the $[(^{\text{MeBim2}}\text{NNN})\text{RuCl}(\text{PPh}_3)_2]\text{Cl}$ (0.5 mol %)-catalyzed reactions in the presence of 0.75 equivalents of KOH using 7.5 equivalents of methanol. Additionally, selective β -dimethylation of 1-phenylethanol could be achieved in the $[(^{\text{MeBim2}}\text{NNN})\text{RuCl}(\text{PPh}_3)_2]\text{Cl}$ (0.5 mol %)-catalyzed reactions in the presence of 2 equivalents of Na using 24.8 equivalents of methanol at 140 °C. The synthetic protocol could be successfully implemented to bring about the β -methylation and selective β -dimethylation of about 35 substrates.

Figure 2.9: Time-profile of the methylation of 2-phenyl ethanol, Reaction condition: 7.5 mmol of CH_3OH , 5 μmol (5.2 mg, 0.5 mol%) **2.10b**, 0.75 mmol KOH at 140 °C and (a) 0.25 mmol of **2.1**, 90 μL 1,4 dioxane was added, (b) 0.75 mmol of **2.1** 30 μL 1,4 dioxane was added, (c) 0.833 mmol of **2.1**, 20 μL 1,4 dioxane was added and (d) 1 mmol of **2.1**.

Figure 2.10: Time-profile of the methylation of 2-phenyl ethanol, Reaction condition: 1 mmol of **2.1**, 7.5 mmol of CH_3OH , 0.75 mmol KOH and (a) 5 μmol (5.2 mg, 0.5 mol%) **2.10b**, (b) 3 μmol (3.12 mg, 0.3 mol%) **2.10b** and (c) 1 μmol (1.04 mg, 0.1 mol%) **2.10b** at 140 °C.

Valuable information has been obtained from detailed and systematic mechanistic studies. The reactions are catalyzed by well-defined molecular catalysts as inferred from mercury-drop experiments, which are further fortified by kinetic experiments that indicate linear dependence of the rate of product formation on the concentrations of both the pincer–ruthenium catalyst and 2-phenylethanol. Deuterium labeling studies indicate a secondary KIE of 1.56, which is suggestive of the unlikely participation of C–H activation in the rate-determining step (RDS), though it is involved in the catalytic cycle. Not surprisingly, DFT studies demonstrate that the dehydrogenolysis involving σ -bond metathesis of methanol with the Ru–H species with concomitant evolution of hydrogen is the RDS with a barrier of 24.06 kcal/mol. The evolved hydrogen was detected by GC during the analysis of the contents of the headspace of the reaction vessel. The resting state of the cycle comprises the lowest-energy intermediates, including the Ru–H species and the Ru–OMe species, which were detected by NMR and HRMS analysis.

Scheme 2.15. Plausible mechanism involved in the **2.10b**-catalyzed transformation of **2.16** to **2.22** and associated energy (ΔG_{140}) profile.

Scheme 2.16. Plausible mechanism involved in the **2.10b**-catalyzed transformation of **2.22** to **2.3** and associated energy (ΔG_{140}) profile.

2.5. Experimental Section

2.5.1. General procedures and materials

All manipulations were carried out under an argon atmosphere. All the chemicals, including NaOH, KOH, NaO^tBu, KO^tBu, Na₂CO₃, K₂CO₃, Na, CDCl₃, CD₃OD, 1- and 2-phenylethanol and their derivatives, and the ruthenium precursors RuCl₃.xH₂O and [RuCl₂(*p*-cymene)]₂, were purchased either from Sigma-Aldrich, Merck, or Alfa Aesar and used as such. All catalytic reactions were carried out in argon using oven-dried glassware. The 1-phenylethanol derivatives that were not commercially available were prepared according to the literature procedure.²⁶ Methanol was dried and distilled under argon according to the literature procedure.²⁷ Solvents such as toluene, tetrahydrofuran, and hexane were dried via double distillation over Na/benzophenone prior to the experiment.²⁷ The ruthenium precursor RuCl₂(PPh₃)₃ and complexes **2.6a–d**, **2.10a**, and **2.10b** were prepared according to the literature protocol.^{23f}

2.5.2. Physical measurements

¹H, ¹³C{¹H}, ¹⁹F, and ³¹P NMR spectra were recorded on a Bruker ASCEND 600 operating at 600 MHz for ¹H, 150 MHz for ¹³C{¹H}, 564 MHz for ¹⁹F, and 243 MHz for ³¹P; on a Bruker AVANCE 500 operating at 500 MHz for ¹H, 125 MHz for ¹³C{H}, 470 MHz for ¹⁹F, and 203 MHz for ³¹P; or on a Bruker AVANCE 400 operating at 400 MHz for ¹H, 100 MHz for ¹³C{¹H}, 377 MHz for ¹⁹F, and 162 MHz for ³¹P. Chemical shifts (δ) are reported here in parts per million, and spin–spin coupling constants (J) are reported in Hertz. The multiplicity data are reported as s–singlet, d–doublet, t–triplet, m–multiplet, q–quartet, and brs–broad singlet. X-ray crystallographic data were acquired on a Bruker D8 Venture single-crystal X-ray diffractometer using graphite-monochromatized Mo K α radiation. The data refinement and cell reductions were carried out by the Bruker SAINT program.²⁴ Structures were further solved and refined by the full matrix leastsquares method using SHELXL-14.²⁵ HRMS measurements were done using an Agilent Accurate-Mass Q-TOF ESI-MS 6520 spectrometer. GC-MS analysis was carried out on an Agilent 5977B GC/MSD instrument. GC analysis was performed on an Agilent 7820 GC instrument fitted with an Agilent Front SS7 inlet N₂ HP-PLOT Q column (30 m \times 530 μ m \times 40 μ m) using the following methods: Agilent 7820 GC back detector; detector temperature (TCD), 250 °C; detector temperature (FID), 300 °C; inlet temperature, 40 °C; time at starting temperature, 0 min; ramp, 40 °C/min up to 250 °C; hold time, 5 min; flow rate (carrier), 25 mL/min (N₂); split ratio, 195. The derivatives of **3** and **5** were separated using a CombiFlash NextGen 100 system.

2.5.3. General procedure for pincer–ruthenium-catalyzed methylation of 2-phenylethanol (2.1)

A 5 mL Schlenk flask containing **2.10b** (5.2 mg, 5 μ mol), KOH (42 mg, 0.75 mmol), 2-phenylethanol (120 μ L, 1 mmol), and CH₃OH (0.303 mL, 7.5 mmol) under an argon atmosphere was heated at 140 °C for 24 h. The reaction mixture was then cooled to room temperature, and toluene (50 μ L, 4.7 μ mol) was added with constant stirring. An aliquot (typically 10 mg) was withdrawn from reaction mixture and added into an NMR tube containing CDCl₃ (0.5 mL). The yield of **2.3** was determined by ¹H NMR spectroscopy using toluene as a standard.²⁸ Methanol from the reaction mixture was removed under reduced pressure. The mixture was then diluted with dichloromethane and H₂O followed by separation of the organic layer, which was subsequently dried over anhydrous Na₂SO₄ prior to removal under reduced pressure. The crude mixture was then purified on a flash chromatography system with a column containing 230–400 mesh silica using hexane and ethyl acetate as the eluent.

2.5.4. General procedure for pincer–ruthenium-catalyzed methylation of 1-phenylethanol (2.2)

To a 5 mL Schlenk flask containing 1-phenylethanol (120 μ L, 1 mmol), and CH₃OH (1 mL, 24.8 mmol) Na (45.96 mg, 2 mmol) was added under ice-cold condition under an argon atmosphere. (**Caution:** Na reacts with water violently to produce H₂ gas, which is highly flammable. The Na metal should be handled under the surface of paraffin oil under argon and stored in paraffin oil in a tightly sealed container to avoid contact with skin and eyes.) After the exothermic reaction had ceased, the reaction mixture was brought to room temperature then **2.10b** (5.2 mg, 5 μ mol) was added and subsequently heated at 140 °C for 24 h. The reaction mixture was then cooled to room temperature, and toluene (50 μ L, 0.470 mmol) was added with constant stirring. An aliquot (typically 10 mg) was withdrawn from reaction mixture and added into an NMR tube containing CDCl₃ (0.5 mL). The yields of **2.4** and **2.5** were determined by ¹H NMR spectroscopy using toluene as a standard.²⁸ Methanol from the reaction mixture was removed under reduced pressure. The mixture was then diluted with dichloromethane and H₂O followed by separation of the organic layer, which was subsequently dried over anhydrous Na₂SO₄ prior to removal under reduced pressure. The crude mixture was then purified on a flash chromatography system with a column containing 230–400 mesh silica using hexane and ethyl acetate as the eluent.

2.5.5. General procedure for the kinetic study of the **2.10b**-catalyzed methylation of alcohols

(a) Variation in the amount of **2.1**

To four 5 mL Schlenk flasks containing **2.10b** (5.2 mg, 5 μ mol), KOH (42 mg, 0.75 mmol), CH₃OH (0.303 mL, 7.5 mmol), and the standard mesitylene (50 μ L, 0.359 mmol) under an argon atmosphere were added various amounts of 2-phenylethanol (30–120 μ L, 0.25–1 mmol) using 1,4-dioxane (0.0–90 μ L) as a makeup solvent to maintain a total volume of 0.473 mL. The reaction mixture was then heated at 140 °C. At regular intervals (Figures 2.S73–76, Figure 2.9), an aliquot (typically 10 mg) was withdrawn from reaction mixture and added to an NMR tube containing CDCl₃ (0.5 mL). The yield of **2.3** was determined by ¹H NMR spectroscopy using mesitylene as the standard.²⁸

(b) Variation in the catalyst **2.10b** loading

To three 5 mL Schlenk flasks containing 2-phenylethanol (120 μ L, 1 mmol), KOH (42 mg, 0.75 mmol), CH₃OH (0.303 mL, 7.5 mmol), and the internal standard mesitylene (50 μ L, 0.359 mmol) under an argon atmosphere, were added various amounts of catalyst **2.10b** (1.0–5.2 mg, 1–5 μ mol). The reaction mixture was then heated at 140 °C. At regular intervals (Figures 2.S76–78, Figure 2.10), an aliquot (typically 10 mg) was withdrawn from reaction mixture and added to an NMR tube containing CDCl₃ (0.5 mL). The yield of **2.3** was determined by ¹H NMR spectroscopy using mesitylene as the standard.²⁸

2.5.6. Synthesis of complex ((*p*-F-C₆H₄)₂NNN)RuCl₂(PPh₃) (**2.7**)

In a 10 mL pear-shaped Schlenk flask, RuCl₂(PPh₃)₃ (0.298 g, 0.311 mmol) and ligand **2.7'** (0.100 g, 0.311 mmol) were dissolved in dry, distilled THF (5 mL), and the solution was refluxed for 16 h. The solvent was evaporated under reduced pressure, and the deep-red-colored solid was washed with diethyl ether (5 \times 4 mL) followed by hexane (5 \times 4 mL). The resulting solid was then dried under vacuum and isolated as a deep-red solid in 88% yield (0.207 g). ¹H NMR (400 MHz, CDCl₃, 25 °C): δ 7.99 (s, 2H, N=CH), 7.57 (dd, *J* = 8.3, 4.9 Hz, 4H, Ar), 7.35 (d, *J* = 7.6 Hz, 2H, Ar), 7.20 (q, *J* = 6.9 Hz, 1H, Ar), 7.11–7.06 (m, 9H, Ar), 6.98 (t, *J* = 8.4 Hz, 4H, Ar), 6.85 (t, *J* = 6.9 Hz, 6H, Ar). ¹³C{¹H} NMR (151 MHz, DMSO-d₆, 25 °C): δ 167.17, 162.43, 160.98, 160.81, 147.03, 132.36 (d, *J* = 9.6 Hz), 130.49 (d, *J* = 43.8 Hz), 128.88, 127.23 (d, *J* = 9.2 Hz), 126.58 (d, *J* = 8.4 Hz), 126.13, 114.42 (d, *J* = 22.5 Hz) (Ar). ³¹P NMR (162 MHz, CDCl₃): δ 31.90. ¹⁹F NMR (377 MHz, CDCl₃): δ -113.19. HRMS (ESI): *m/z*

calculated for $[2.7 - Cl]^+ = [C_{37}H_{28}ClF_2N_3PRu]^+$: 720.0721, found 720.0725; m/z calculated for $[(2.7 - Cl + CH_3CN)]^+ = [C_{39}H_{31}ClF_2N_4PRu]^+$: 761.0986, found 761.0982.

2.5.7. Synthesis of complex $((p\text{-CF}_3\text{-C}_6\text{H}_4)_2\text{NNN})\text{RuCl}_2(\text{PPh}_3)$ (2.8)

In a 10 mL pear-shaped Schlenk flask, $\text{RuCl}_2(\text{PPh}_3)_3$ (0.205 g, 214 μmol) and ligand **2.8'** (0.090 g, 214 μmol) were dissolved in dry, distilled THF (5 mL), and the solution was refluxed for 16 h. The solvent was evaporated under reduced pressure, and the blackish-colored solid was washed with diethyl ether (5×4 mL) followed by hexane (5×4 mL). The resulting solid was dried under vacuum and isolated as a blackish solid in 88% yield (0.207 g). ^1H NMR (600 MHz, CDCl_3 , 25 $^\circ\text{C}$): δ 8.08 (s, 2H, N=CH), 7.65 (d, $J = 8.0$ Hz, 4H, Ar), 7.54 (d, $J = 8.1$ Hz, 4H, Ar), 7.40 (d, $J = 7.8$ Hz, 2H, Ar), 7.13 (t, $J = 7.8$ Hz, 1H, Ar), 7.12–7.01 (m, 9H, Ar), 6.80 (t, $J = 7.6$ Hz, 6H, Ar). $^{13}\text{C}\{^1\text{H}\}$ NMR (151 MHz, CDCl_3): δ 165.74, 161.57, 153.28, 132.70 (d, $J = 9.6$ Hz), 130.45 (d, $J = 4.2$ Hz), 130.19 (d, $J = 8.8$ Hz), 129.51, 128.31, 127.79 (d, $J = 9.8$ Hz), 126.21, 125.74 (q, $J = 3.6$ Hz), 125.47, 125.04, 123.24 (Ar). ^{31}P NMR (243 MHz, CDCl_3 , 25 $^\circ\text{C}$): δ 30.74. ^{19}F NMR (565 MHz, CDCl_3 , 25 $^\circ\text{C}$): δ -62.25. HRMS (ESI): m/z calculated for $[2.8 - Cl]^+ = [C_{39}H_{28}ClF_6N_3PRu]^+$: 820.0657, found 820.0675; m/z calculated for $[(2.8 - Cl + CH_3CN)]^+ = [C_{41}H_{31}F_6N_4PRu]^+$: 861.0922, found 861.0939.

2.5.8. Synthesis of complex $((p\text{-OMe-C}_6\text{H}_4)_2\text{NNN})\text{RuCl}_2(\text{PPh}_3)$ (2.9)

In a 10 mL pear-shaped Schlenk flask, $\text{RuCl}_2(\text{PPh}_3)_3$ (0.167 g, 0.174 μmol) and ligand **2.9'** (0.060 g, 0.174 μmol) were dissolved in dry, distilled THF (5 mL), and the solution was stirred for 16 h at room temperature. The solvent was evaporated under reduced pressure, and the blackish-colored solid was washed with diethyl ether (5×4 mL) followed by hexane (5×4 mL). The resulting solid was dried under vacuum and isolated as a blackish solid in 78% yield (0.105 g). NMR analysis showed the presence of two isomers, *cis* (major) and *trans* (minor), in a 2:1 ratio. ^1H NMR (400 MHz, CDCl_3 , 25 $^\circ\text{C}$): δ 8.14 (s, 2H, N=CH), 7.95 (s, 1H, Ar), 7.74 (d, $J = 7.9$ Hz, 2H, Ar), 7.58 (d, $J = 8.9$ Hz, 2H, Ar), 7.35–7.27 (m, 8H, Ar), 7.18 (dd, $J = 13.6$, 8.2 Hz, 7H, Ar), 7.12–7.03 (m, 10H, Ar), 6.83 (t, $J = 7.2$ Hz, 6H, Ar), 6.37 (d, $J = 8.8$ Hz, 4H, Ar), 3.88 (s, 3H, OMe), 3.68 (s, 6H, OMe). $^{13}\text{C}\{^1\text{H}\}$ NMR (151 MHz, CDCl_3 , 25 $^\circ\text{C}$): δ 166.44 (d, $J = 2.2$ Hz), 162.93, 161.77, 160.04, 159.74, 158.73, 148.37, 144.57, 135.45 (d, $J = 9.7$ Hz), 134.26, 134.02, 132.94 (d, $J = 9.3$ Hz), 132.77, 132.20 (d, $J = 10.0$ Hz), 132.05 (d, $J = 2.8$ Hz), 130.91, 130.61, 129.02, 128.68 (d, $J = 7.4$ Hz), 128.57, 128.35, 127.54 (d, $J = 9.7$ Hz), 127.10 (d, $J = 8.9$ Hz), 126.34, 124.92, 123.70, 123.32, 113.79, 113.63 (Ar), 55.82 (OMe), 55.42. ^{31}P

NMR (243 MHz, CDCl₃): δ 33.21, 29.10. HRMS (ESI): m/z calculated for [2.9 – Cl]⁺ = [C₃₉H₃₄ClN₃O₂PRu]⁺ : 744.1121, found 744.1131; m/z calculated for [2.9 – Cl + CH₃CN]⁺ = [C₄₁H₃₇ClN₄O₂PRu]⁺ : 785.1386, found 785.1381.

2.5.9. Characterization of the products

2.3

2-Phenylpropan-1-ol (2.3).^{11c} Colorless liquid. ¹H NMR (600 MHz, CDCl₃): δ 7.27–7.24 (m, 2H, Ar), 7.20–7.14 (m, 3H, Ar), 3.61 (d, J = 7.1 Hz, 2H, -CH₂), 2.89–2.84 (m, 1H, -CH), 1.70 (br s, 1H, -OH), 1.21 (d, J = 7.1 Hz, 3H, -CH₃). ¹³C{¹H} NMR (151 MHz, CDCl₃): δ 143.83, 128.72, 127.59, 126.75 (Ar), 68.76 (-CH₂), 42.52 (-CH), 17.69 (-CH₃).

2.3a

2-(p-Tolyl)propan-1-ol (2.3a).^{11a} Colorless liquid. ¹H NMR (600 MHz, CDCl₃): δ 7.18–7.11 (m, 4H), 3.68 (d, J = 7.2 Hz, 2H, -CH₂), 2.94–2.89 (m, 1H, -CH), 2.33 (s, 3H, -CH₃), 1.54 (br s, 1H, -OH), 1.26 (d, J = 7.0 Hz, 3H, -CH₃). ¹³C{¹H} NMR (151 MHz, CDCl₃): δ 140.68, 136.38, 129.49, 127.49 (Ar), 77.37, 68.91 (-CH₂), 42.16 (-CH₃), 21.13 (-CH₃ (C₆H₄)), 17.79 (-CH₃).

2.3b

2-(4-Chlorophenyl)propan-1-ol (2.3b).^{11c} Colorless liquid. ¹H NMR (600 MHz, CDCl₃): δ 7.32–7.28 (m, 2H), 7.20–7.13 (m, 2H), 3.93–3.47 (m, 2H), 2.96–2.90 (m, 1H), 1.62 (brs, 1H), 1.26 (d, J = 7.0 Hz, 3H). ¹³C{¹H} NMR (151 MHz, CDCl₃): δ 142.35, 132.47, 128.97, 128.85 (Ar), 68.63 (-CH₂), 41.99 (-CH), 17.67 (-CH₃).

2-(3-Chlorophenyl)propan-1-ol (2.3c).^{11f} Colorless liquid. ¹H NMR (600 MHz, CDCl₃): δ 7.30–7.20 (m, 3H, Ar), 7.14 (m, 1H, Ar), 3.70 (d, 2H, -CH₂), 2.97–2.91 (m, 1H, -CH), 1.76 (brs, 1H, -OH), 1.28 (d, *J* = 7.0 Hz, 3H, -CH₃). ¹³C{¹H} NMR (151 MHz, CDCl₃): δ 146.09, 134.50, 129.94, 127.74, 126.91, 125.89 (Ar), 68.46, (-CH₂), 42.32 (-CH), 17.58 (-CH₃).

2-(*m*-Tolyl)propan-1-ol (2.3f).^{13b} Colorless liquid. ¹H NMR (600 MHz, CDCl₃): δ 7.31–7.17 (m, 1H, Ar), 7.11–6.98 (m, 3H, Ar), 3.69 (d, *J* = 6.9 Hz, 2H, -CH₂), 2.94–2.89 (m, 1H, -CH), 2.36 (s, 3H, -CH₃(C₆H₄)), 1.65 (brs, 1H, -OH), 1.27 (d, *J* = 7.0 Hz, 3H, -CH₃). ¹³C{¹H} NMR (151 MHz, CDCl₃): δ 143.74, 138.30, 128.63, 128.39, 127.53, 124.55 (Ar), 68.75 (-CH₂), 42.47 (CH), 21.57 (-CH₃(C₆H₄)), 17.73 (-CH₃).

2-(2-Methoxyphenyl)propan-1-ol (2.3g). Colorless liquid. ¹H NMR (600 MHz, CDCl₃): δ 7.23–7.20 (m, 2H, Ar), 6.96 (td, *J* = 7.5, 1.1 Hz, 1H, Ar), 6.88 (d, *J* = 8.0 Hz, 1H, Ar), 3.83 (s, 3H, -OMe), 3.77–3.66 (m, 2H, -CH₂), 3.47–3.41 (m, 1H, -CH), 1.69 (brs, 1H, -OH), 1.26 (d, *J* = 7.1 Hz, 3H, -CH₃). ¹³C{¹H} NMR (151 MHz, CDCl₃): δ 157.46, 131.89, 127.57, 127.46, 120.95, 110.73 (Ar), 68.00 (-OMe), 55.53 (-CH₂), 35.32 (-CH), 16.68, -CH₃).

2-(3-Fluorophenyl)propan-1-ol (2.3h).³² Colorless liquid. ¹H NMR (600 MHz, CDCl₃): δ 7.30–7.27 (m, 1H, Ar), 7.02 (d, *J* = 7.7 Hz, 1H, Ar), 6.98–6.89 (m, 2H, Ar), 3.79–3.56 (m, 2H,

-CH₂), 2.99–2.93 (m, 1H, -CH), 1.62 (brs, 1H, -OH), 1.27 (d, $J = 7.0$ Hz, 3H, -CH₃). ¹³C{¹H} NMR (151 MHz, CDCl₃): δ 164.02, 162.40, 146.64, 130.19, 130.13, 123.35, 123.33, 114.48, 114.34, 113.73, 113.59 (Ar), 68.58 (-CH₂), 42.38 (-CH), 17.60 (-CH₃). ¹⁹F NMR (565 MHz, CDCl₃): δ -113.11.

2-(*o*-Tolyl)propan-1-ol (2.3i).^{11c} Colorless liquid. ¹H NMR (600 MHz, CDCl₃): δ 7.24–7.09 (m, 4H, Ar), 3.95–3.50 (m, 2H, -CH₂), 3.29–3.23 (m, 1H, -CH), 2.37 (s, 3H, -CH₃(C₆H₄)), 1.50 (brs, 1H, -OH), 1.25 (d, $J = 6.9$ Hz, 3H, -CH₃). ¹³C{¹H} NMR (151 MHz, CDCl₃): δ 141.86, 136.57, 130.71, 126.52, 126.42, 125.56 (Ar), 68.16 (-CH₂), 37.34 (-CH), 19.76 (-CH₃(C₆H₄)), 17.67 (-CH₃).

2-(2-Chlorophenyl)propan-1-ol (2.3j). Colorless liquid. ¹H NMR (600 MHz, CDCl₃): δ 7.37 (dd, $J = 8.0, 1.3$ Hz, 1H, Ar), 7.30–7.23 (m, 2H, Ar), 7.18–7.15 (m, 1H, Ar), 3.80 (dd, $J = 10.8, 6.5$ Hz, 1H, -CH₂), 3.71 (dd, $J = 10.8, 6.3$ Hz, 1H, -CH₂), 3.57–3.51 (m, 1H, -CH), 1.69 (brs, 1H, -OH), 1.29 (d, $J = 7.0$ Hz, 3H, -CH₃). ¹³C{¹H} NMR (151 MHz, CDCl₃): δ 141.02, 134.42, 129.88, 127.74, 127.71, 127.18 (Ar), 67.33 (-CH₂), 38.20 (-CH), 17.61 (-CH₃).

2-(4-Methoxyphenyl)propan-1-ol (2.3k).^{11c} Colorless liquid. ¹H NMR (600 MHz, CDCl₃): δ 7.20–7.05 (m, 2H, Ar), 6.97–6.59 (m, 2H, Ar), 3.79 (s, 3H, -OMe), 3.77–3.45 (m, 2H, -CH₂), 3.16–2.69 (m, 1H, -CH), 1.63 (brs, 1H, -OH), 1.25 (d, $J = 7.0$ Hz, 3H, -CH₃). ¹³C{¹H} NMR (151 MHz, CDCl₃): δ 158.45, 135.73, 128.51, 114.16 (Ar), 68.91 (-OMe), 55.39 (-CH₂), 41.68 (-CH), 17.85 (-CH₃).

2-(3-Methoxyphenyl)propan-1-ol (2.3l).^{11a} Colorless liquid. ¹H NMR (600 MHz, CDCl₃): δ 7.26 (t, $J = 7.6$ Hz, 1H, Ar), 6.87–6.75 (m, 3H, Ar), 3.82 (s, 3H, -OMe), 3.69 (d, 2H, -CH₂), 2.95–2.90 (m, 1H, -CH), 1.87 (brs, 1H, -OH), 1.27 (d, $J = 7.1$ Hz, 3H, -CH₃). ¹³C{¹H} NMR (151 MHz, CDCl₃): δ 159.87, 145.55, 129.68, 119.89, 113.56, 111.77 (Ar), 68.65 (-OMe), 55.24 (-CH₂), 42.57 (-CH), 17.66 (-CH₃)

2-(Naphthalen-1-yl)propan-1-ol (2.3o).^{11c} Off-white solid. ¹H NMR (600 MHz, CDCl₃): δ 8.16 (d, $J = 8.6$ Hz, 1H, Ar), 7.89 (d, $J = 8.1$ Hz, 1H, Ar), 7.76 (d, $J = 8.1$ Hz, 1H, Ar), 7.56–7.46 (m, 3H, Ar), 7.42 (d, $J = 7.3$ Hz, 1H, Ar), 3.97–3.80 (m, 3H, -CH₂, -CH), 1.77 (brs, 1H, -OH), 1.55–1.33 (m, 3H). ¹³C{¹H} NMR (151 MHz, CDCl₃): δ 139.67, 134.10, 132.05, 129.09, 127.15, 126.13, 125.64, 123.16, 123.13 (Ar), 68.17 (-CH₂), 36.45 (-CH), 17.94 (-CH₃).

2-Methyl-1-phenylpropan-1-ol (2.5).^{11a,13b} Colorless liquid. ¹H NMR (600 MHz, CDCl₃): δ 7.36–7.25 (m, 5H, Ar), 4.36 (d, $J = 6.9$ Hz, 1H, -CHOH), 2.00–1.92 (m, 1H, -CH), 1.88 (brs, 1H, -OH), 1.01 (d, $J = 6.7$ Hz, 3H, -CH₃), 0.80 (d, $J = 6.8$ Hz, 3H, -CH₃). ¹³C{¹H} NMR (151 MHz, CDCl₃): δ 143.77, 128.30, 127.53, 126.69 (Ar), 80.17 (-CHOH), 35.38 (-CH), 19.12 (-CH₃), 18.36 (-CH₃).

1-(4-Bromophenyl)-2-methylpropan-1-ol (55a).¹⁷ Colorless liquid. ¹H NMR (600 MHz, CDCl₃): δ 7.36–7.25 (m, 4H, Ar), 4.36 (d, *J* = 6.9 Hz, 1H, -CHOH), 1.99–1.92 (m, 1H, -CH), 1.75 (brs, 1H, -OH), 1.00 (d, *J* = 6.7 Hz, 3H, -CH₃), 0.80 (d, *J* = 6.8 Hz, 3H, -CH₃). ¹³C{¹H} NMR (151 MHz, CDCl₃): δ 143.78, 128.31, 127.53, 126.70 (Ar), 80.17 (-CHOH), 35.38 (-CH), 19.12 (-CH₃), 18.36 (-CH₃).

1-(4-(tert-Butyl)phenyl)-2-methylpropan-1-ol (5.5f). Colorless liquid. ¹H NMR (600 MHz, CDCl₃): δ 7.36–7.35 (m, 2H, Ar), 7.26–7.23 (m, 2H, Ar), 4.32 (d, *J* = 7.1 Hz, 1H, -CHOH), 1.99–1.91 (m, 1H, -CH), 1.79 (brs, 1H, -OH), 1.324 (s, 9H, -C(CH₃)₃) 1.02 (d, *J* = 6.6 Hz, 3H, -CH₃), 0.80 (d, *J* = 6.8 Hz, 3H, -CH₃). ¹³C{¹H} NMR (151 MHz, CDCl₃): δ 150.45, 140.81, 126.42, 126.40, 125.22 (Ar), 80.06 (-CHOH), 35.30 (-CH), 34.63 (-C(CH₃)₃), 31.51 (-C(CH₃)₃), 19.24 (-CH₃), 18.52 (-CH₃).

2-Methyl-1-(naphthalen-2-yl)propan-1-ol (5.5i).^{13b} Off-white solid. ¹H NMR (400 MHz, CDCl₃): δ 7.87–7.80 (m, 3H, Ar), 7.76 (d, *J* = 1.7 Hz, 1H, Ar), 7.51–7.44 (m, 3H, Ar), 4.54 (d, *J* = 6.9 Hz, 1H, -CHOH), 2.12–2.03 (m, 1H, -CH), 1.80 (brs, 1H, -OH), 1.05 (d, *J* = 6.7 Hz, 3H, -CH₃), 0.85 (d, *J* = 6.9 Hz, 3H, -CH₃). ¹³C{¹H} NMR (151 MHz, CDCl₃): δ 141.25, 133.31, 133.10, 128.09, 128.06, 127.79, 126.19, 125.86, 125.54, 124.77 (Ar), 80.29 (-CHOH), 35.33 (-CH), 19.27 (-OH), 18.36 (-CH₃).

1-(4-Fluorophenyl)-2-methylpropan-1-ol (5.5j).¹⁷ Colorless liquid. ¹H NMR (600 MHz, CDCl₃): δ 7.36–7.30 (m, 3H, Ar), 7.29–7.25 (m, 1H, Ar), 4.37 (d, *J* = 6.9 Hz, 1H, -CHOH),

2.0–1.92 (m, 1H, -CH), 1.61 (brs, 1H, -OH), 1.00 (d, $J = 6.7$ Hz, 3H, -CH₃), 0.80 (d, $J = 6.8$ Hz, 3H, -CH₃). ¹³C{¹H} NMR (151 MHz, CDCl₃): δ 143.77, 128.34, 127.57, 126.70 (Ar), 80.21 (-CHOH), 35.41 (-CH), 19.15 (-CH₃), 18.38 (-CH₃). ¹⁹F NMR (565 MHz, CDCl₃): δ -121.88.

1-(3-Methoxyphenyl)-2-methylpropan-1-ol (5.5l).⁴ Colorless liquid. ¹H NMR (600 MHz, CDCl₃): δ 7.28–7.24 (m, 1H, Ar), 6.90–6.83 (m, 2H, Ar), 6.85–6.81 (m, 1H, Ar), 4.34 (d, $J = 6.9$ Hz, 1H, -CHOH), 1.99–1.91 (m, 1H, -CH), 1.88 (brs, 1H, -CHOH), 1.01 (d, $J = 6.7$ Hz, 3H, -CH₃), 0.82 (d, $J = 6.8$ Hz, 3H, -CH₃). ¹³C{¹H} NMR (151 MHz, CDCl₃): δ 159.69, 145.56, 129.28, 119.11, 112.93, 112.21 (Ar), 55.33 (-CHOH), 35.34 (-CH), 19.20 (-CH₃), 18.33 (CH₃).

2-Methyl-1-(p-tolyl)propan-1-ol (5.5o).^{11a,17} Colorless liquid. ¹H NMR (600 MHz, CDCl₃): δ 7.21–7.13 (m, 4H, Ar), 4.31 (d, $J = 7.0$ Hz, 1H, -CHOH), 2.35 (s, 3H, -CH₃(C₆H₄)), 1.98–1.90 (m, 1H, -CH), 1.86 (brs, 1H, -OH), 1.01 (d, $J = 6.7$ Hz, 3H, -CH₃), 0.79 (d, $J = 6.8$ Hz, 3H, -CH₃). ¹³C{¹H} NMR (151 MHz, CDCl₃): δ 140.82, 137.13, 128.99, 126.63 (Ar), 80.07 (-CHOH), 35.32 (-CH), 21.22 (-CH₃(C₆H₄)), 19.12 (-CH₃), 18.48 (-CH₃).

1-(4-Methoxyphenyl)-2-methylpropan-1-ol (5.5q).¹⁷ Colorless liquid. ¹H NMR (600 MHz, CDCl₃): δ 7.24–7.20 (m, 2H, Ar), 6.89–6.85 (m, 2H, Ar), 4.28 (d, $J = 7.2$ Hz, 1H, -CHOH), 3.80 (s, 3H, -OCH₃), 1.98–1.88 (m, $J = 6.7$ Hz, 1H, -CH), 1.75 (brs, 1H, -OH), 1.00 (d, $J = 6.7$ Hz, 3H, -CH₃), 0.76 (d, $J = 6.8$ Hz, 3H, -CH₃). ¹³C{¹H} NMR (151 MHz, CDCl₃): δ 159.05,

135.98, 127.83, 113.69 (Ar), 79.87 (-OMe), 55.37 (-CHOH), 35.39 (-CH), 19.07 (-CH₃), 18.63 (-CH₃).

1-(3-Chlorophenyl)-2-methylpropan-1-ol (5.5r).⁴ Colorless liquid. ¹H NMR (600 MHz, CDCl₃): δ 7.22–7.17 (m, 3H, Ar), 7.13–7.11 (m, 1H, 1H, Ar), 4.31 (d, J = 6.6 Hz, 1H, -CHOH), 1.93–1.83 (m, 1H, -CH), 1.63 (brs, 1H, -OH), 0.91 (d, J = 6.7 Hz, 3H, -CH₃), 0.76 (d, J = 6.8 Hz, 3H, -CH₃). ¹³C{¹H} NMR (151 MHz, CDCl₃): δ 145.85, 134.28, 129.58, 127.65, 126.83, 124.86 (Ar), 79.41 (-CHOH), 35.40 (-CH), 19.09 (-CH₃), 18.02 (-CH₃).

2.5.10. Computational details

The geometries of all the considered complexes were fully optimized using the DFT (PBE)²⁹ method with the Gaussian-09 package.³⁰ The LANL2DZ³¹ and 6-311G(d,p) basis sets with a polarization function were used for the metal (Ru) and nonmetal atoms, respectively. The method and basis set were selected according to previous reports on pincer-ruthenium complexes.^{18,20,22} The transition states were located using the synchronous transit-guided quasi-Neon (QST2) Genecp (gen keyword with the effective core potential) to define the basis set. The empirical dispersion-GD3 was used in all molecular geometry optimization and energy computations. Frequency calculations were used to characterize the obtained stationary points as minimum-energy structures or transition states based on the number of imaginary frequencies. Single-point calculations were performed to calculate the relative free energy values at 140 °C (ΔG_{140}).

Supporting information (containing NMR spectra and of pure compound and metal-complexes, HRMS data, GC plot) for chapter II is available as appendix I and can be found at

Chapter- III

Pincer-Ruthenium Catalyzed Direct Formation of Fuel-Grade Alkanes via Decarboxylative Coupling of Alcohols

The contents of this chapter have been adapted from “Pincer-Ruthenium-Catalyzed Direct Formation of Fuel-Grade Alkanes via a Net-Decarboxylative Coupling of Alcohols” by Nandi, P. G.; Maity, P.; Kumar, A. *ACS Catal* **2025**, *15*, 543-556.

3.1. Introduction

There has been a flurry of activities towards sustainable conversion of easily available biomass into biofuels and chemical feedstock to counter the raw-material deficit that is inevitable owing to the rapid depletion of fossil fuels.¹ Towards this end, the chemistry of C-C bond formation has been an evergreen area of synthetic organic chemistry that provides a convenient and versatile route to natural products, fine chemicals, fuels, pharmaceuticals and agrochemicals.² Typically, these otherwise unsurmountable C-C bond formation reactions are mainly accomplished by organometallic³⁻⁷ and radical pathways⁸ *via* transition metal-catalyzed activation of C-X (X = Cl, Br and I) bonds. Another convenient route to C-C bond formation that has received special attention recently due to its atom-economical and green nature has been the alcohol re-functionalization reaction *via* hydrogen auto-transfer⁹ or the hydrogen-borrowing strategy¹⁰ where water is the only by-product. In particular, the direct transformation of alcohols derived from biomass into biofuel and long chain alkanes are not only sustainable but also attractive despite its tremendously challenging nature owing to the difficult to achieve hydrogenation of the decarboxylated alkene.^{11,12}

Scheme 3.1. General mechanistic pathway for the transformation of low-molecular weight alcohols to high-molecular weight alkanes *via* decarboxylative coupling.

The first step of these low-molecular weight alcohol to higher-molecular weight alkane transformations involve the dehydrogenation of the low-molecular weight alcohol to produce aldehydes which couple in presence of a base to give α , β -unsaturated aldehyde *via* aldol-condensation (Scheme 3.1). This is followed by decarboxylation to produce allyl anion and

then alkene which ideally then should react with the H₂ released in the previous step in a metal

Current Work Single-Step One-pot

Scheme 3.2. Catalytic methods reported for the decarboxylative coupling of alcohols.

catalyzed reaction to produce fuel-grade higher molecular weight alkane as the desired product (Scheme 3.1).

A majority of the reported catalytic systems (Scheme 3.2) halt at the stage of formation of higher-molecular weight alkene and an additional effort is required to hydrogenate the alkene to alkane (Scheme 3.2). Efficient catalytic methods are hence vital to selectively produce alkane without the need of additional hydrogen and/or catalysts. The decarboxylation of alcohols to alkene or alkane has been reported in past by Ishii and Obora,¹³ Liu,¹⁴ Srimani,¹⁵ Jhonson¹⁶ and Tu.¹⁷

Scheme 3.3. Iridium catalyzed decarboxylative coupling of 2-phenylethanol to 1,3-diphenylpropane.¹³

In 2011, Ishii and Obora carried out the formation of fluorescent active α, ω -diaryl alkanes from ω -aryl alcohols as the model substrates using iridium salt $(\text{Cp}^*\text{IrCl}_2)_2$ (Scheme 3.3).¹³ They have reported α, ω -diarylalkane (**3.3**) formation from ω -arylethanol (**3.1**) by dehydrogenation/ β -alkylation (step1) and subsequent dehydrogenation/decarboxylation (step 2) either by one step (direct) (route A) or sequential step (route B) (Scheme 3.3). The α, ω -diaryl propanes were synthesized in good to moderate yield from the homo-coupling of 2-aryl ethanols using commercially available iridium catalyst $(\text{Cp}^*\text{IrCl}_2)_2$ (1 mol%), KO^tBu (0.4 equivalents) in *p*-xylene (0.5 mL) at 120 °C for 4 hours. Similarly, when the reaction was carried out in 1,4 dioxane (1 mL) for 24 h, **3.3'** was observed instead of **3.3** in good to moderate yield. In presence of $[(\text{Cp}^*\text{IrCl}_2)_2]$ (2)/ $[\{\text{IrCl}(\text{cod})\}_2]$ (2) **3.3'** was converted to **3.3** with dppe ligand, K₂CO₃ (20 mol%) in mesitylene (1.5 mL) at 160 °C for 24 h with good to moderate yields (Scheme 3.3).

In 2018, Johnson and co-workers used commercially available $\text{RuCl}_2(\text{PPh}_3)_3$ (1 mol%) for the conversion of a variety of 2-phenylethanols to the corresponding alkenes using 1.2 mol% of +DPPP ((1,3-*bis*(diphenylphosphino) propane) ligand, 0.6 equivalents NaO^tBu in toluene under reflux for 24 h (Scheme 3.4).¹⁶

Scheme 3.4. Ruthenium catalyzed decarboxylative coupling of 2-phenylethanol to 1,3-diphenylpropene.¹⁶

In 2018, Liu and co-workers, for the first time studied the homo as well as hetero coupling of alcohols to corresponding alkenes using PNP pincer-Mn catalysts **3.Mn1**. In the first step 2-phenylethanol were converted to the corresponding alkenes with very good yields, using **3.Mn1** (0.2 mol%), NaOH (0.6 equivalents) in xylene under reflux conditions for 16 hours (Scheme 3.5).¹⁴ A follow-up hydrogenation catalyzed by Ni@SiO₂-Al₂O₃ under 20 bar H₂ in methanol was carried out at 50 °C in a separate pot to get good to moderate yield of alkanes (Scheme 3.5).

Scheme 3.5. The **3.Mn1** catalyzed decarboxylative coupling of 2-phenylethanol to 1,3-diphenylpropenes and Ni@SiO₂-Al₂O₃ catalyzed formation of 1,3-diphenylpropane and its derivatives.¹⁴

In 2021, Tu and co-workers carried out the direct formation of 1,3-diphenylpropane from 2-phenylethanol using **3.Ir1** (0.8 mol%) in presence of 0.6 equivalents NaOH in *tert*-amyl alcohol for 24 h in 140 °C (Scheme 3.6).¹⁷ The catalyst **3.Ir1** catalyzed the hydrogenation of 1,3-diphenylpropene without any additional molecular hydrogen (H₂) and also the catalytic system is very suitable for both homo and hetero coupling of alcohols. Using the highly selective protocol a variety of alcohol substrates were upgraded to corresponding alkanes with good to moderate yield.

Scheme 3.6. The **3.Ir1** catalyzed direct formation of 1,3-diphenylpropanes from 2-phenylethanol.¹⁷

Recently, Srimani developed a methodology for the transformation of 2-phenylethanol to the corresponding alkanes using (SNS)Ru (**3.Ru1**) catalytic system in two sequential steps (Scheme 3.7).¹⁵ In the first step **3.Ru1**(0.5 mol%) catalyzed the transformation of 2-phenylethanol to 1,3-diphenylpropene with 0.6 equivalents NaOH in toluene at 140 °C for 24 h. In the second step, **3.Ru1**(0.5 mol%) catalyzed the transformation 1,3-diphenylpropene to 1,3-diphenylpropane with 0.5 equivalents of KO^tBu at 100 °C in presence of externally added molecular H₂ (3 bar). This methodology was useful for the both homo and hetero coupling of a variety of alcohol substrates (Scheme 3.7).¹⁵

Scheme 3.7. The **3.Ru1** catalyzed decarboxylative coupling of 2-phenylethanol to 1,3-diphenylpropenes and sequential hydrogenation of 1,3-diphenylpropane and its derivatives .¹⁵

3.2. Objectives of the current work

A comprehensive literature survey reveals that the pincer complexes are very much active for the activation of alcohol molecules. Other than the independent reports by Ishi¹³ and Tu¹⁷ with Ir based catalysts, there are no investigations on the formation of alkanes starting from alcohols using a single-step one-pot strategy, to the best of our knowledge. In particular, all the reported Ru^{15,16} based catalysts have led to the formation of alkenes starting from alcohols and wherever alkanes were reported, these were accomplished in an additional¹⁵ hydrogenation step with molecular hydrogen (Scheme 3.2).

We have demonstrated the utility of NNN pincer-Ru catalysts based on *bis(imino)pyridine* ligands and 2,6-*bis(benzimidazole-2-yl)pyridine* ligands in catalyzing various value addition of alcohols such as N-alkylation,¹⁸ alcohol reforming,¹⁹ β -alkylation,²⁰ β -methylation²¹ and Geurbet reactions.^{20,22} Notably, all of these reactions involved a dehydrogenation step¹⁸⁻²² while some of the reactions involved a secondary hydrogenation step^{18,20-22} utilizing the hydrogen evolved during the former step. It would be interesting to examine the activity of these NNN pincer-Ru catalysts based on *bis(imino)pyridine* ligands and 2,6-*bis(benzimidazole-2-yl)pyridine* ligands towards decarboxylative coupling of alcohols to higher alkanes which also requires a very similar tandem occurrence of dehydrogenation and hydrogenation reactions.

In this context, in the current work, the activity of a series of new and known NNN pincer-Ru catalysts of the type (^{R2}NNN)RuCl₂L (R = ⁱPr, ^tBu, Cy, Ph, *p*-F-C₆H₄, *p*-OMe-C₆H₄ and L = PPh₃, CO and CH₃CN) based on *bis(imino)pyridine* ligands and (^{RBim2}NNN)RuCl₂L₂ (R = H and Me, L = PPh₃ and CO) based on 2,6-*bis(benzimidazole-2-yl)pyridine* ligands have been investigated towards the decarboxylative coupling of alcohols to alkanes. While most of the complexes were unselective giving alkene/alkane mixtures, the complex (^{MeBim2}NNN)RuCl₂(PPh₃)₂ based on 2,6-*bis(benzimidazole-2-yl)pyridine* ligand demonstrated high activity (ca. 88 ± 3% yield) with exclusive formation of the alkane (1,3-diphenyl propane) starting from 2-phenyl ethanol in the presence of 0.5 equivalents of NaOH in toluene at 140 °C within 5 h of reaction. The (^{MeBim2}NNN)RuCl₂(PPh₃)₂ catalyzed transformation of 2-phenyl ethanol to 1,3-diphenyl propane has been probed in detail from both synthetic and mechanistic point of view. To the best of our knowledge, this has been the first example of a Ru based catalyst for the direct upgradation of alcohols to alkanes using a single-step one-pot decarboxylative tandem transfer hydrogenation strategy.

3.3. Result and discussions

3.3.1. Synthesis and characterization of pincer-ruthenium complexes based on bis(imino)pyridine ligands

The NNN pincer ruthenium complexes **3.8a-f**, **3.9a-d**, **3.10a**, **3.10c-d**, **3.11a-b** and **3.12a-b** (Figure 3.1) were synthesized following our previously reported protocol.^{19a, 20-24} The new complexes **3.9e-f** with CO as ancillary ligands were synthesized in good yields by treatment of the corresponding ligands²¹ with [Ru(*p*-cymene)Cl₂]₂ under CO atmosphere with THF at reflux for 16h (Scheme 3.8). Similarly, **3.10b** and **3.10e-f** with NCCH₃ as ancillary ligand were synthesized in acetonitrile under argon atmosphere (Scheme 3.8).

Scheme 3.8. Protocol for the synthesis of **3.9e-f** and **3.10b,e-f**^a.

^aThe molecular structures of **3.9e**, **3.9f**, **3.10b** and **3.10e** are provided as ORTEP figures drawn at 50% probability. All the hydrogen atoms are omitted for the sake of clarity.

All the new complexes **3.9e-f**, **3.10b** and **3.10e-f** were fully characterized by ¹H, ¹³C{¹H}, ¹⁹F NMR spectroscopy and HRMS studies. The ¹³C{¹H} NMR spectrum of **3.9e** and **3.9f** exhibited the chemical shift of CO group at δ = 201 ppm and δ = 204 ppm respectively (Figure 3.S3 and 3.S5). The FT-IR studies revealed prominent bands at 1967 cm⁻¹ and 1945 cm⁻¹ that correspond to the CO stretching in **3.9e** and **3.9f** respectively (Figure 3.7, 3.8 and 3.S13, 3.S14). While the complexes **3.10b** and **3.10f** exist as a single isomer with the NCCH₃ ligand *trans* to the pyridyl N, the ¹H NMR studies revealed that the complex **3.10e** exists as two isomers in the ratio 1.00: 0.75 where the major isomer has the NCCH₃ ligand *trans* to the pyridyl N and the minor isomer

has the NCCH_3 ligand *trans* to one of the chloride ligands. The HRMS analysis of **3.9e**, **3.9f**, **3.10b**, **3.10e** and **3.10f** demonstrated prominent peaks at $m/z = 485.9749$, 510.0155 , 423.0893 , 499.0051 and 523.0460 that correspond to $[\mathbf{3.9e} - \text{Cl}]^+$, $[\mathbf{3.9f} - \text{Cl}]^+$, $[\mathbf{3.10b} - \text{Cl}]^+$, $[\mathbf{3.10e} - \text{Cl}]^+$ and $[\mathbf{3.10f} - \text{Cl}]^+$ (Figure 3.S15-3.S32). For SCXRD studies, good quality crystals of **3.9e** was obtained by layering its solution in $\text{CDCl}_3 + \text{DCM}$ with hexane, while suitable crystals of **3.9f**, **3.10b** and **3.10e** were obtained by slow evaporation of the corresponding solvent from their solution in DMSO, CDCl_3 and DCM respectively. The complexes **3.9e**, **3.9f**, **3.10b** and **3.10e** crystallized with a space-group of $P21/c$, $C2/c$, $P-1$ and $C2/c$ respectively (Table 3.4 and 3.S1).

3.3.2. Pincer-ruthenium catalyzed decarboxylative coupling of 2-phenylethanol to 1,3-diphenyl propane

The catalytic upgradation of lower-molecular weight alcohols to higher-molecular weight alkanes were initiated using 2-phenylethanol (**3.1**) as model substrate using 0.5 mol% (MeBim^2NNN) $\text{RuCl}_2(\text{PPh}_3)_2$ (**3.11b**) in presence of various bases at 140°C in toluene (Table 3.1). In the presence of an equivalent of NaOH at 140°C , the yield of 1,3-diphenylpropane (**3.3**) increases to $>99\%$ with increase in the loading of **3.11b** from 0.25 mol% to 1 mol% (entries 1-4, Table 3.1).

At 1 mol% loading of **3.11b** in 0.5 mL toluene, though the exclusive selectivity towards **3.3** was retained, the yield of **3.3** however decreased upon lowering the NaOH loading (entries 4-8, Table 3.1). To strike a good balance between the high yield of **3.3** and minimal base loading, the optimization was continued at a NaOH loading of 0.5 equivalents as in entry 6, Table 3.1.

Further studies with 1 mol% loading of **3.11b** in the presence of 0.5 equivalents of NaOH at varying dilutions in toluene revealed that the catalytic decarboxylation of **3.1** to **3.3** was more efficient in 0.5 mL toluene (entry 6 vs. entries 9-11, Table 3.1). Upon repeating the reaction under the new optimized conditions (1 mol% **3.11b**, 0.5 equivalent NaOH in 0.5 mL solvent), it was observed that productivity of **3.11b** in toluene was superior than the corresponding productivity of **3.11b** in other solvents such as 1,4-dioxane, *tert*-butanol, THF, *m*-xylene and *tert*-amyl alcohol (entry 6 vs. entries 12-16, Table 3.1). Entry 6, Table 3.1 thus continues to be the optimized condition till this stage. While the performance of **3.11b** was relatively poor in the presence of bases such as NaO^tBu , KO^tBu and KOH (entries 18-20, Table 3.1), no reactivity was observed when the **3.11b** catalysed decarboxylation was carried out in the presence of

presence of Na_2CO_3 , K_2CO_3 , Cs_2CO_3 , NaHCO_3 and KHCO_3 (entries 21-25, Table 3.1).

Figure 3.1. Pincer-Ru complexes investigated in the current study.

The **3.11b** catalyzed decarboxylation of **3.1** to **3.3** in the presence of 0.5 equivalents of NaOEt resulted in a selectivity and productivity that was comparable to the corresponding results obtained in the presence of 0.5 equivalents of NaOH (entry 6 vs. entry 17, Table 3.1 and Table 3.S3). As the latter is readily available and more economical, further studies on the **3.11b** catalyzed decarboxylation was carried out in the presence of 0.5 equivalents of NaOH in 0.5 mL toluene at 140 °C.

Table 3.1. The 3.11b catalyzed decarboxylation of 2-phenylethanol to 1,3-diphenylpropane under varying conditions^a

Entry	Catalyst (X mol %)	Base (Y equivalents)	Solvent (Z mL)	% Yield ^b		Selectivity of 3.3 (%) ^d

^aReaction conditions, unless specified otherwise: 0.5 mmol of **3.1**, 0.5 equivalents of NaOH and 1 mol % ruthenium catalysts at 140 °C for 24 h in a 15 mL high pressure tube with toluene (0.5 mL) under air. ^bDetermined by ¹H NMR analysis using mesitylene as the standard. ^cSelectivity is calculated as Selectivity = (3.3*100)/(3.3+3.2).

ligand demonstrated the excellent activity among all the considered pincer-Ru complexes and

their precursors both in terms of selectivity and productivity (entry 20 vs. rest of the entries in Table 3.2 and Table 3.S4).

Table 3.3. Decarboxylation of 2-phenylethanol to 1,3-diphenyl propane catalyzed by various ruthenium complexes^a

^aReaction conditions, unless specified otherwise: 0.5 mmol of **3.1**, 0.5 equivalents (10 mg, 0.25 mmol) of NaOH and 1 mol % (5.2 mg, 5 μmol) **3.11b** at 140 °C for 24 h in a 15 mL high pressure tube with toluene (0.5 mL) under air. Yields determined by ¹H NMR analysis using mesitylene as the standard. ^bIsolated yields. ^cRatio of precursor alcohols of structures marked in maroon to corresponding structures marked in blue are 4:1.

Notably, reaction of **3.1** under the optimized conditions but in the absence of any catalyst lead

to exclusive formation of the alkene **3.2** in 27% yield (entry 27, Table 3.1). However, there was no reactivity when the reaction was repeated under the optimized conditions, but this time without using a base (entry 28, Table 3.1). These observations along with the inference obtained from control experiments (*vide infra*) sheds light on the key role that the catalyst **3.11b** plays in leading to the selective formation of alkane **3.3** in high yields.

The formulated protocol on the **3.11b** catalyzed decarboxylation was then investigated for various derivatives of 2-phenylethanol not only for homocoupling but also for heterocoupling (Table 3.3). In general, functional groups at *p*-position of the arene ring on the derivatives of **3.1** gave good yields of the corresponding **3.3** based alkanes (**3.3a**, **3.3f**, **3.3h** and **3.3j**) with **3.3g**, **3.3m** and **3.3n** being the only exceptions. The yields of alkane derivatives **3.3b**, **3.3c**, **3.3d**, **3.3e**, **3.3i**, **3.3k** and **3.3l** which had substituents either in the *m*-position or in the *o*-position were slightly lower than the corresponding alkanes with *p*-substituents. A variety of heterocoupled alkane products **3.3r-3.3w** could also be accessed in moderately good yields (Table 3.3).

3.3.3. Control experiments and mechanistic insight

Various control experiments were performed with an objective to attain a clear understanding on the plausible mechanism involved in the **3.11b** (1 mol%) catalyzed decarboxylation of **3.1** to **3.3** in the presence of 0.5 equivalents of NaOH. Analysis of the head space of the vessel containing the reaction mixture under the optimized conditions (entry 6, Table 3.1 and entry 20, Table 3.2) revealed the evolution of hydrogen during the reaction (equation 1, Scheme 3.4 and Figures 3.9) essentially pointing towards dehydrogenation of **3.1** to the corresponding aldehyde **3.1'** as one of the primary steps. Apart from the formation of **3.3**, the generation of formic acid is also observed from the ¹H NMR analysis of the crude reaction mixture corresponding to equation **3.1** of Scheme 3.9 which is indicative of an associated decarboxylative step in the upgradation of **3.1** to **3.3**. The aldehyde **3.1'** which is the dehydrogenated version of **3.1** when subjected to optimized reaction conditions in the absence of a base leads to α,β -unsaturated aldehyde **3.4** (equation 2, Scheme 3.9) which when treated with NaOH under the optimized conditions but in the absence of **3.11b** resulted in the formation of the alkene **3.2** (equation 5, Scheme 3.9). Notably alkene **3.2** could be accessed exclusively in 92% yield by treating the aldehyde **3.1'** under the optimized conditions either in the presence

(equation 3, Scheme 3.9) or in the absence (equation 4, Scheme 3.9) of catalyst **3.11b**. These observations indicate that the formation of alkene **3.2** starting from the aldehyde **3.1'** is typically uncatalyzed and base mediated.

Scheme 3.9. Control experiments.

(equation 7, Scheme 3.9). The former observation is indicative of the key role that phosphine dissociation plays in the generation of the active catalyst **3.8ac/3.11bc** (Scheme 3.10) while the latter highlights the exclusively molecular homogeneous nature of the catalytic system.

Further evidence for the exclusive role of well-defined molecular nature of the catalyst system has been obtained from kinetic experiments that were conducted by varying the concentration of **3.11b**. Using the initial-rate method, it was observed that the rate of the **3.11b** catalyzed decarboxylation of **3.1** to **3.3** had a first-order dependence on the concentration of **3.11b** (Figure 3.2a and Figures 3.S38-S42). A linear dependence of rate on the concentration of NaOH was also observed by employing the initial rate method (Figure 3.2b and Figures 3.S43-S47).

Figure 3.3. Free energy (ΔG_{140}) profile for the **3.8a** and **3.11b** catalyzed dehydrogenation of **3.1**.

The inferences drawn from the catalytic studies and control experiments have been instrumental in arriving at a plausible mechanism which is depicted in Scheme 3.10 where the pincer framework of the most efficient catalyst **3.11b** and the least efficient catalyst **3.8a** are represented only by their NNN ligating section for the sake of simplicity. One of the key events in the **3.8a/3.11b** decarboxylative upgradation of **3.1** to **3.3** is the dehydrogenation of **3.1** to the corresponding aldehyde **3.1'** which involves sequential β -hydride elimination from **3.8aa/3.11ba** followed by dehydrogenolysis (σ -bond metathesis) of **3.8ac/3.11bc** with **3.1** via

TS-3.8ab/TS-3.11bb and **TS-3.8ad/TS-3.11bd** respectively (Scheme 3.10). For the overall endergonic reaction ($\Delta G_{140} = 2.16$ kcal/mol), both the β -hydride elimination and the σ -bond metathesis are kinetically favorable with the most efficient catalyst **3.11b** by 5.06 kcal/mol and 3.34 kcal/mol respectively when compared with the least efficient system based on **3.8a** (Figure 3.3). Notably, for the dehydrogenation of **3.1** catalyzed by **3.11b** and **3.8a**, the dehydrogenolysis is the rate-determining step (RDS) with a barrier of 22.81 kcal/mol and 24.49 kcal/mol respectively (Figure 3.3).

Figure 3.4. Free energy (ΔG_{140}) profile for the **3.8a** and **3.11b** catalyzed hydrogenation of **3.2**.

In the presence of NaOH, the aldehyde **3.1'** undergoes a decarboxylative coupling (Scheme 3.1) to yield the internal olefin **3.2**. The olefin **3.2** could then insert into the Ru-H bond in **3.8ac/3.11bc** to yield the intermediate **3.8af/3.11bf** via **TS-3.8ae/TS-3.11be** (Scheme 3.10).

While using **3.11b**, this step is almost thermodynamically neutral with a barrier of 13.83 kcal/mol. On the other hand, use of **3.8a** leads to an endergonic step ($\Delta G_{140} = 1.84$ kcal/mol) with a high barrier of 27.81 kcal/mol (Figure 3.4). The intermediate **3.8af/3.11bf** either undergo an alcoholysis (**3.8af/3.11bf**→**TS-3.8ah/TS-3.11bh**→**3.8aa/3.11ba**→**TS-3.8ab/TS-3.11bb**→**3.8ac/3.11bc**) with a molecule of **3.1** or a hydrogenolysis (**3.8af/3.11bf**→**TS-3.8ag/TS-3.11bg**→**3.8ac/3.11bc**) with hydrogen to complete the catalytic cycle. Figure 3.4 shows that both the sub-steps **3.8af/3.11bf**→**TS-3.8ah/TS-3.11bh**→**3.8aa/3.11ba** and **3.8aa/3.11ba**→**TS-3.8ab/TS-3.11bb**→**3.8ac/3.11bc** involved in the alcoholysis fragment are clearly kinetically more favored with **3.11b**.

Figure 3.5. HRMS of the reaction mixture containing 2-phenylethanol (**3.1**) (0.6 mL, 0.5 mmol), NaOH (10 mg, 0.25 mmol), toluene (0.5 mL) and **3.11b** (5.2 mg, 5 μ mol) maintained at (a) room temperature ($t = 0$ h) and (b) 140 $^{\circ}$ C for 1 h.

Similarly, the barrier for hydrogenolysis using **3.11b** (TS- **3.11bg**; $\Delta G_{140}^{\ddagger} = 19.75$ kcal/mol) is much lower than the corresponding barrier with **3.8a** (TS-**3.8ag**; $\Delta G_{140}^{\ddagger} = 27.58$ kcal/mol) (Figure 3.4). When one compares the cycle for the transformation **3.2** \rightarrow **3.3** the path **3.8ac** \rightarrow TS-**3.8ae** \rightarrow **3.8af** \rightarrow TS-**3.8ah** \rightarrow **3.8aa** \rightarrow TS- **3.8ab** \rightarrow **3.8ac** via the alcoholysis step is more favored than the hydrogenolysis path **3.8ac** \rightarrow TS-**3.8ae** \rightarrow **3.8af** \rightarrow TS-**3.8ag** \rightarrow **3.8ac** while using the relatively poor catalyst **3.8a** with the formation of TS- **3.8ae** ($\Delta G_{140}^{\ddagger} = 27.81$ kcal/mol) as the RDS (Figure 3.4). Further comparison with the rate-determining barrier (TS- **3.8ad**; $\Delta G_{140}^{\ddagger} = 24.49$ kcal/mol) of the previous step **3.1** \rightarrow **3.1'** (Figure 3.3), reveals that the formation of TS-**3.8ae** ($\Delta G_{140}^{\ddagger} = 27.81$ kcal/mol, Figure 3.4) during the transformation **3.2** \rightarrow **3.3** is the overall RDS for the **3.8b** catalyzed reaction.

Figure 3.6. (a) The ^{31}P NMR spectrum of **3.11b** in CDCl_3 . (b) The ^{31}P NMR spectrum of the reaction mixture containing 2-phenylethanol (**3.1**) (0.6 mL, 0.5 mmol), NaOH (10 mg, 0.25 mmol), **3.11b** (10.4 mg, 0.01 mmol) and toluene (0.5 mL) maintained at room temperature ($t = 0$ h) under air (c) The ^{31}P NMR spectrum of the reaction mixture containing 2-phenylethanol (**3.1**) (0.6 mL, 0.5 mmol), NaOH (10 mg, 0.25 mmol), **3.11b** (10.4 mg, 0.01 mmol) and toluene (0.5 mL) maintained at 140°C ($t = 5$ min) under air (d) The hydride region of the ^1H NMR spectrum corresponding to reaction conditions provided in Figure 3.6c.

On the other hand, with the most efficient catalyst **3.11b**, the route **3.11bc**→**TS-3.11be**→**3.11bf**→**TS-3.11bg**→**3.11bc** involving the hydrogenolysis step is energetically more favorable than the alcoholysis path **3.11bc**→**TS-3.11be**→**3.11bf**→**TS-3.11bh**→**3.11ba**→**TS-3.11bb**→**3.11bc**, with the formation of **TS-3.11bg** ($\Delta G_{140}^\ddagger = 19.75$ kcal/mol) being the RDS (Figure 3.4). In the **3.11b** catalyzed reaction, as the rate-determining barrier for the step **3.2**→**3.3** (Figure 3.4) is 3.06 kcal/mol lower than the corresponding rate-determining barrier of the step **3.1**→**3.1'** (Figure 3.3), the formation of **TS-3.11bd** ($\Delta G_{140}^\ddagger = 22.81$ kcal/mol) in the dehydrogenation step is the overall RDS. Gratifyingly, the intermediate **3.11bc** which has the lowest energy among the species involved in the RDS **3.11bc**→**TS-3.11bd**→**3.11ba** has been detected as its PPh_3 adduct **3.11bca** in the HRMS analysis (Figure 3.5) and NMR analysis

(Figure 3.6) of the reaction mixture under the optimized conditions (entry 6, Table 3.1 and entry 20, Table 3.2).

Clearly, the sterically more open catalyst **3.11b** has a lower overall rate-determining barrier (**TS-3.11bd**; $\Delta G_{140}^\ddagger = 22.81$ kcal/mol) in comparison with the corresponding overall barrier (**TS-3.8ae**; $\Delta G_{140}^\ddagger = 27.81$ kcal/mol) of the relatively bulky catalyst **3.8a**. Not surprisingly the **3.11b** outperforms **3.8a** both in terms of selectivity and productivity (entry 1 vs. entry 20, Table 3.2 and Table 3.S4) during the catalytic upgradation of lower-molecular weight alcohol **3.1** to higher-molecular weight alkane **3.3**.

3.4. Conclusion

A series of new and known NNN pincer-Ru catalysts of the type $(R^2NNN)RuCl_2L$ ($R = iPr, tBu, Cy, Ph, p-F-C_6H_4, p-OMe-C_6H_4$ and $L = PPh_3, CO$ and CH_3CN) based on *bis*(imino)pyridine ligands and $[(^{RBim^2}NNN)RuClL_2]Cl$ ($R = H$ and $Me, L = PPh_3$ and CO) based on 2,6-*bis*(benzimidazole-2-yl)pyridine ligands have been utilized to examine the decarboxylative coupling of lower-molecular weight alcohols to higher-molecular weight alkanes.

While a majority of the considered pincer-Ru complexes including the Ru precursors failed to demonstrate good activity towards the formation of the desired alkane, 1 mol% of $(^{MeBim^2}NNN)RuCl_2(PPh_3)_2$ based on 2,6-*bis*(benzimidazole-2-yl)pyridine ligand demonstrated excellent activity giving up to 91% yield with 100% selectivity towards the alkane (1,3-diphenyl propane) starting from 2-phenyl ethanol within 5 h of reaction in the presence of 0.5 equivalents of NaOH in toluene at 140 °C.

Detailed mechanistic studies were indicative of the involvement of α, β -unsaturated aldehydes along with the evolution of hydrogen (detected by GC) and formic acid (detected by 1H NMR) during the reaction. A first-order dependence of initial rate on both the catalyst concentration and the concentration of base was observed in the $[(^{MeBim^2}NNN)RuCl(PPh_3)_2]Cl$ catalysed transformation of 2-phenyl ethanol to 1,3-diphenyl propane. This points to the homogeneous and well-defined molecular nature of the catalyst which was also fortified by catalyst poisoning experiments with Hg.

DFT studies nicely complement the experimental findings and indicate that the dehydrogenolysis step leading to the formation of 2-phenyl acetaldehyde and the resting state

Figure 3.7: IR spectrum of 3.9e.

Figure 3.8: IR spectrum of 3.9f.

Figure 3.9: Evidence for the evolution of H₂ in dehydrogenation of 2-phenylethanol (**3.1**) catalyzed by **3.11b** (1 mol%) at 140 °C *via* GC analysis.

Figure 3.10: Time-profile of the decarboxylative coupling of 2-phenylethanols. Reaction condition: 0.5 mmol of **3.1**, 0.25 mmol (0.5 equivalents, 10 mg) NaOH, 0.5 mL toluene at 140 °C and (a) 1.25 μmol (1.3 mg, 0.25 mol%) **3.11b**, (b) 2.5 μmol (2.6 mg, 0.5 mol%) **3.11b**, (c) 3.75 μmol (3.9 mg, 0.75 mol%) **11b**, (d) 5 μmol (5.2 mg, 1 mol%) **3.11b** and (e) 10 μmol (10.4 mg, 2 mol%) **3.11b**.

Figure 3.11: Time-profile of the decarboxylative coupling of 2-phenylethanols. Reaction condition: 0.5 mmol of **3.1**, 5 μ mol (5.2 mg, 1 mol%) **3.11b**, 0.5 mL toluene at 140 $^{\circ}$ C and (a) 0.125 mmol (5 mg, 0.25 equivalents) NaOH, (b) 0.25 mmol (10 mg, 0.5 equivalents) NaOH, (c) 0.375 mmol (15 mg, 0.75 equivalents) NaOH, (d) 0.5 mmol (20 mg, 1 equivalents) NaOH, (e) 0.625 mmol (25 mg, 1.25 equivalents) NaOH and (f) 0.75 mmol (30 mg, 1.5 equivalents) NaOH.

(^{Me}Bim²NNN)RuHCl is the rate-determining step with a barrier of 22.81 kcal/mole at 140 $^{\circ}$ C. The resting state [(^{Me}Bim²NNN)RuH(PPh₃)₂]Cl has been experimentally trapped as the PPh₃ adduct which has been detected by HRMS analysis and NMR studies. In comparison to the rate-determining dehydrogenolysis step of the cycle involving most active catalyst [(^{Me}Bim²NNN)RuCl(PPh₃)₂]Cl, the corresponding cycle with the least active catalyst (ⁱPr²NNN)RuCl₂(PPh₃) involved insertion of 1,3-diphenyl propene into the Ru-H bond as the RDS which is kinetically unfavorable by 5.00 kcal/mol and gives only 14% of 1,3-diphenyl propane at 25% selectivity. To the best of our knowledge, this has been the first example of a Ru based catalyst for the upgradation of alcohols to alkanes directly without the need of an additional hydrogenation step. Selective production of jet-fuel-grade alkanes starting from lower-molecular weight alcohols in a single-step one-pot strategy has been demonstrated here which offers exciting avenues for catalytic production of jet-fuel-grade hydrocarbons.

3.5. Experimental section

3.5.1. General procedure and materials

All manipulations were carried out under argon conditions. All the additives (NaOH, KOH, NaO^tBu, KO^tBu, Na₂CO₃, NaHCO₃, K₂CO₃, KHCO₃, Cs₂CO₃ and NaOEt), solvents (tetrahydrofuran, diethyl ether, hexane, toluene, CDCl₃ and DMSO-d₆), substrates (2-phenyl ethanol and their derivatives), the ruthenium precursors [RuCl₂(*p*-cymene)]₂ and RuCl₃.xH₂O were purchased either from Sigma–Aldrich or MERCK or Alfa Aesar and used as such. All catalytic reactions were carried out in air using oven-dried glassware. The solvent such as tetrahydrofuran, diethyl ether, toluene and hexane were dried *via* double distillation over Na/benzophenone prior to the experiment²⁵

3.5.2. Physical Measurements

¹H, ¹³C{¹H}, ¹⁹F and ³¹P NMR spectra were recorded on a Bruker ASCEND 600 operating at 600 MHz for ¹H, 150 MHz for ¹³C{¹H}, 564 MHz for ¹⁹F and at 243 MHz for ³¹P or on a Bruker AVANCE 500 operating at 500 MHz for ¹H, 125 MHz for ¹³C{¹H}, 470 MHz for ¹⁹F and at 203 MHz for ³¹P or on a Bruker AVANCE 400 operating at 400 MHz for ¹H, 100 MHz for ¹³C{¹H}, 377 MHz for ¹⁹F and at 162 MHz for ³¹P. Chemical shifts (δ) are reported here in ppm, spin – spin coupling constant (J) are expressed in Hz and the peak multiplicity is reported as s – singlet, d – doublet, t – triplet, m – multiple and q – quartet. FT-IR spectra were recorded using a PerkinElmer spectrophotometer. X-ray crystallographic data were acquired on a Bruker D8 Venture single-crystal X-ray diffractometer using graphite monochromated Mo K α radiation. The data refinement and cell reductions were carried out by the Bruker SAINT program.²⁴ Structures were further solved and refined by the full matrix least squares method using SHELXL-14.25 HRMS measurements were done using an Agilent Accurate-Mass Q-TOF ESI-MS 6520. GC-MS analysis was carried out on an Agilent 5977B GC/MSD. GC analysis were performed on an Agilent 7820 – GC instrument fitted with an Agilent Front SS7 inlet N₂ HP – PLOT Q column (30 m × 530 μm × 40 μm) using the following methods. Agilent 7820 – GC back detector, Detector temperature (TCD): 250 °C, Detector temperature (FID): 300 °C, Inlet temperature: 40 °C, Time at starting temp: 0 min, ramp: 40 °C/min upto 250 °C, Hold time = 5 min, Flow rate (carrier): 25 mL/min (N₂), Split ratio: 195. The homo-coupled derivatives of **3.3** were separated using CombiFlash NextGen 100 System and hetero-coupled derivatives were separated using column chromatography.

3.5.3. General procedure for pincer-ruthenium catalyzed decarboxylative homo-coupling of 2-phenyl ethanol (3.1)

A 15 mL pressure tube containing **3.11b** (5.2 mg, 5 μ mol), NaOH (10 mg, 0.25 mmol), 2-phenyl ethanol (60 μ L, 0.5 mmol) and toluene (0.5 mL) under air was sealed and the reaction mixture was heated at 140 $^{\circ}$ C for 24 h. The reaction mixture was then cooled to room temperature and mesitylene (50 μ L) was added with constant stirring. An aliquot (typically 10 mg) was withdrawn from reaction mixture and added to a NMR tube containing CDCl₃ (0.5 mL). The yield was determined by ¹H NMR using mesitylene as a standard.²⁶ The reaction mixture was then diluted with water and washed with dichloromethane. The organic layer was separated and dried over anhydrous Na₂SO₄. The solvent was subsequently removed under reduced pressure. The crude product was then purified using flash chromatography system with a column containing 230-400 mesh silica using hexane as eluent.

3.5.4. General procedure for pincer-ruthenium catalyzed decarboxylative hetero-coupling of 2-phenyl ethanol (3.1)

A 15 mL pressure tube containing **3.11b** (26 mg, 25 μ mol), NaOH (50 mg, 0.25 mmol), 2-phenyl ethanol or its derivative (2 mmol) and another 2-phenyl ethanol derivative (0.5 mmol) in toluene (2 mL) under air was sealed and the reaction mixture was heated at 140 $^{\circ}$ C for 24 h. The reaction mixture was then cooled to room temperature and mesitylene (50 μ L, 0.359 mmol) was added with constant stirring. An aliquot (typically 10 mg) was withdrawn from reaction mixture and added to a NMR tube containing CDCl₃ (0.5 mL). The yield was determined by ¹H NMR using mesitylene as a standard.²⁶ The reaction mixture was then diluted with water and washed with dichloromethane. The organic layer was collected and dried over anhydrous Na₂SO₄. The solvent was subsequently removed under reduced pressure. The crude product was then purified by column chromatography using 230-400 mesh silica with hexane as eluent.

3.5.5. General procedure for 3.11b catalyzed decarboxylative coupling of 2-phenyl ethanol (3.1)– kinetic study

(a) Catalyst (3.11b) loading variation

To five 15 mL pressure tubes containing 2-phenyl ethanol (60 μ L, 0.5 mmol), NaOH (10 mg, 0.25 mmol), toluene (0.5 mL) and the internal standard mesitylene (50 μ L, 0.359 mmol) under air various amounts of catalyst **3.11b** (1.3 – 10.4 mg, 1.25 - 10 μ mol) were added and sealed.

The reaction mixtures were heated at 140 °C for 24 h. At regular intervals (Figure 3.S38 – Figure 3.S42, Figure 3.10) an aliquot (typically 10 mg) was withdrawn from each of the reaction mixtures and added to a NMR tubes containing CDCl₃ (0.5 mL). The yield was determined by ¹H NMR using mesitylene as a standard.²⁶

(b) Base loading variation

To six 15 mL pressure tubes containing 2-phenyl ethanol (60 μL, 0.5 mmol), **3.11b** (5.2 mg, 5 μmol), toluene (0.5 mL) and the internal standard mesitylene (50 μL, 0.359 mmol) under air, various amounts of NaOH (5 – 30 mg, 0.125 – 0.75 mmol) were added and sealed. The reaction mixtures were heated at 140 °C for 24 h. At regular intervals (Figure 3.S41 and Figure 3.S43 – Figure 3.S47, Figure 3.11) an aliquot (typically 10 mg) was withdrawn from each of the reaction mixtures and added to NMR tubes containing CDCl₃ (0.5 mL). The yield was determined by ¹H NMR using mesitylene as a standard.²⁶

3.5.6. Synthesis of (*p*-F-C₆H₄)₂NNN)RuCl₂(CO) (**3.9e**)

In a 10 ml pear shaped flask, [Ru(*p*-cymene)Cl₂]₂ (0.060 g, 0.0979 mmol) and the ligand **3.13e** (0.0629 g, 0.1959 mmol) were dissolved in dry and distilled THF (5 mL) and the solution was refluxed for 16 h under a CO atmosphere. The solvent was evaporated under reduced pressure, and the brown-coloured solid was washed with diethyl ether (5 × 4 mL). The resulting residue was dried under vacuum and isolated as a brown solid (0.087 g) in 85% yield. ¹H NMR (600 MHz, CDCl₃, 25 °C) δ 8.02 (s, 2H), 7.95 (t, J = 7.8 Hz, 1H), 7.83 (d, J = 7.8 Hz, 2H), 7.57 (dd, J = 8.8, 4.7 Hz, 4H), 7.12 (t, J = 8.5 Hz, 4H). ¹⁹F NMR (565 MHz, CDCl₃, 25 °C) δ -110.74. ¹³C{¹H} NMR (151 MHz, CDCl₃, 25 °C) δ 201.15, 164.05, 163.61, 162.39, 156.82, 148.69, 148.66, 138.91, 124.96, 123.69, 123.63, 116.66, 116.51. Molecular weight: 521.3108, HRMS (ESI): m/z calculated for [**3.9e** – Cl]⁺ = [C₂₀H₁₃ClF₂N₃ORu]⁺ : 485.9759, found 485.9749; m/z calculated for [(**3.9e** – Cl + CH₃CN)⁺ = [C₂₂H₁₆ClF₂N₄ORu]⁺ : 527.0024, found 527.0020; m/z calculated for [**3.9e1** – Cl]⁺ = [C₃₈H₂₆ClF₄N₆Ru]⁺ : 779.0887, found 779.0895; m/z calculated for [**3.9f2** – RuCl₄]²⁺ = [C₃₈H₂₆F₄N₆Ru]²⁺ : 372.0599, found 372.0595.

3.5.7. Synthesis of (*p*-OMe-C₆H₄)₂NNN)RuCl₂(CO) (**3.9f**)

In a 10 ml pear shaped flask, [Ru(*p*-cymene)Cl₂]₂ (0.060 g, 0.0979 mmol) and the ligand **3.13f** (0.0676 g, 0.1959 mmol) were dissolved in dry and distilled THF (5 mL) and the solution was refluxed for 16 h under a CO atmosphere. The solvent was evaporated under reduced pressure,

and the brown-coloured solid was washed with diethyl ether (5×4 mL). The resulting residue was dried under vacuum and isolated as a brown solid (0.085 g) in 80% yield. ^1H NMR (600 MHz, DMSO- d_6 , 25 °C) δ 8.43 (s, 2H), 8.27– 8.23 (m, 1H), 8.13 (d, $J = 7.7$ Hz, 2H), 7.56 (d, $J = 9.0$ Hz, 4H), 7.07 (d, $J = 9.0$ Hz, 4H), 3.83 (s, 6H). $^{13}\text{C}\{^1\text{H}\}$ NMR (151 MHz, DMSO- d_6 , 25 °C) δ 204.13, 165.74, 160.00, 156.00, 145.36, 139.99, 126.01, 123.31, 114.23, 55.65. Molecular weight: 545.3820, HRMS (ESI): m/z calculated for $[\mathbf{3.9f} - \text{Cl}]^+ = [\text{C}_{22}\text{H}_{19}\text{ClN}_3\text{O}_3\text{Ru}]^+$: 510.0158, found 510.0155; m/z calculated for $[(\mathbf{3.9f} - \text{Cl} + \text{CH}_3\text{CN})]^+ = [\text{C}_{24}\text{H}_{22}\text{ClN}_4\text{O}_3\text{Ru}]^+$: 551.0424, found 551.0440; m/z calculated for $[\mathbf{3.9f1} - \text{Cl}]^+ = [\text{C}_{42}\text{H}_{38}\text{ClN}_6\text{O}_4\text{Ru}]^+$: 827.1687, found 827.1733; m/z calculated for $[\mathbf{3.9f2} - \text{RuCl}_4]^{2+} = [\text{C}_{42}\text{H}_{38}\text{N}_6\text{O}_4\text{Ru}]^{2+}$: 396.0999, found 396.1007.

3.5.8. Synthesis of $(^t\text{Bu}_2\text{NNN})\text{RuCl}_2(\text{NCCH}_3)$ (**3.10b**)

In a 10 ml pear shaped flask, $[\text{Ru}(p\text{-cymene})\text{Cl}_2]_2$ (0.060 g, 0.0979 mmol) and the ligand **3.13b** (0.048 g, 0.1959 mmol) were dissolved in dry and distilled acetonitrile (5 mL) and the solution was refluxed for 16 h. The solvent was evaporated under reduced pressure, and the brown-coloured solid was washed with diethyl ether (5×4 mL). The resulting residue was dried under vacuum and isolated as a brown solid (0.075 g) in 84% yield. ^1H NMR (400 MHz, CDCl_3 , 25 °C) δ 8.29 (s, 2H), 7.64 (d, $J = 7.8$ Hz, 2H), 7.49 (t, $J = 7.8$ Hz, 1H), 2.86 (s, 3H), 1.65 (s, 18H). $^{13}\text{C}\{^1\text{H}\}$ NMR (151 MHz, CDCl_3 , 25 °C) δ 162.22, 159.14, 129.26, 126.38, 123.79, 66.50, 30.14, 5.08. Molecular weight: 458.3930, HRMS (ESI): m/z calculated for $[\mathbf{3.10b} - \text{Cl}]^+ = [\text{C}_{17}\text{H}_{26}\text{ClN}_4\text{Ru}]^+$: 423.0889, found 423.0893.

3.5.9. Synthesis of $(p\text{-F-C}_6\text{H}_4)_2\text{NNN})\text{RuCl}_2(\text{NCCH}_3)$ (**3.10e**)

In a 10 ml pear shaped flask, $[\text{Ru}(p\text{-cymene})\text{Cl}_2]_2$ (0.060 g, 0.0979 mmol) and the ligand **3.13e** (0.0629 g, 0.1959 mmol) were dissolved in dry and distilled acetonitrile (5 mL) and the solution was refluxed for 16 h. The solvent was evaporated under reduced pressure, and the brown-coloured solid was washed with diethyl ether (5×4 mL). The residue was dried under vacuum and isolated as a brown solid (0.084 g) in 80 % yield. NMR analysis shows the presence of two isomers as *cis* (minor, NCCH_3 ligand *trans* to one of the Cl ligands) and *trans* (major, NCCH_3 ligand *trans* to pyridyl N) in 1:1.33 ratio. ^1H NMR (600 MHz, CDCl_3 , 25 °C) δ 8.56 (s, 2H), 8.41 (s, 2H), 8.10 (d, $J = 7.5$ Hz, 2H), 7.80 (s, 1H), 7.79 – 7.72 (m, 5H), 7.70 (dd, $J = 8.7, 4.9$ Hz, 3H), 7.55 (t, $J = 7.8$ Hz, 1H), 7.16 (t, $J = 8.1$ Hz, 4H), 7.11 (t, $J = 8.6$ Hz, 3H), 2.51 (s, 3H), 2.44 (s, 2H). ^{19}F NMR (565 MHz, CDCl_3 , 25 °C) δ -111.61, -113.31. $^{13}\text{C}\{^1\text{H}\}$ NMR (151 MHz,

CDCl₃, 25 °C) δ 166.51, 163.80, 163.45, 162.77, 162.13, 161.81, 161.15, 147.89, 147.87, 146.74, 146.73, 134.13, 129.21, 124.98, 124.92, 124.79, 124.73, 123.83, 116.45, 116.30, 115.97, 115.81, 4.77, 4.50. Molecular weight: 534.3538, HRMS (ESI): m/z calculated for **[3.10e – Cl]⁺** = [C₂₁H₁₆ClF₂N₄Ru]⁺ : 499.0075, found 499.0051; m/z calculated for **[(3.10e – Cl + CH₃CN)⁺** = [C₂₃H₁₉ClF₂N₅Ru]⁺ : 540.0340, found 540.0270.

3.5.10. Synthesis of (*p*-OMe-C₆H₄)₂NNN)RuCl₂(NCCH₃) (**3.10f**)

In a 10 ml pear shaped flask, [Ru(*p*-cymene)Cl₂]₂ (0.060 g, 0.0979 mmol) and the ligand **3.13f** (0.0676 g, 0.1959 mmol) were dissolved in dry and distilled acetonitrile (5 mL) and the solution was refluxed for 16 h. The solvent was evaporated under reduced pressure, and the brown-coloured solid was washed with diethyl ether (5 × 4 mL). The residue was dried under vacuum and isolated as a brown solid (0.083 g) in 76% yield. ¹H NMR (600 MHz, DMSO-d₆, 25 °C) δ 8.49 (s, 2H), 8.07 (d, *J* = 7.9 Hz, 2H), 7.92 (t, *J* = 7.9 Hz, 1H), 7.47 (d, *J* = 8.9 Hz, 4H), 7.00 (d, *J* = 8.9 Hz, 4H), 3.80 (s, 6H), 3.34 (s, 4H). ¹³C{¹H} NMR (151 MHz, DMSO-d₆, 25 °C) δ 167.64, 166.43, 159.05, 147.19, 142.89, 126.21, 124.66, 123.01, 114.20, 113.37, 55.48. Molecular weight: 558.4250, HRMS (ESI): m/z calculated for **[3.10f – Cl]⁺** = [C₂₃H₂₂ClN₄O₂Ru]⁺ : 523.0475, found 523.0460; m/z calculated for **[(3.10f – Cl + CH₃CN)⁺** = [C₂₅H₂₅ClN₅O₂Ru]⁺ : 564.0740, found 564.0724.

3.5.11. Characterization of the products

1,3-diphenylpropane (3.3).^{15,17} Colourless liquid, ¹H NMR (600 MHz, CDCl₃) δ 7.32 (t, *J* = 8.3 Hz, 4H, Ar), 7.22 (d, *J* = 7.3 Hz, 6H, Ar), 2.69 (t, *J* = 7.7 Hz, 4H, -CH₂Ar), 2.00 (t, *J* = 7.7 Hz, 2H, -CH₂). ¹³C{¹H} NMR (151 MHz, CDCl₃) δ 142.43, 128.58, 128.44, 125.87 (Ar), 35.58 (-CH₂Ar), 33.08 (-CH₂). GC-MS [M]⁺ : 196.1.

1,3-bis(4-methoxyphenyl)propane (3.3a).^{15,17} Colourless liquid, ¹H NMR (600 MHz, CDCl₃) δ 7.10 (d, *J* = 8.5 Hz, 4H, Ar), 6.83 (d, *J* = 8.6 Hz, 4H, Ar), 3.79 (s, 6H, -OMe), 2.61 – 2.55 (m, 4H, -CH₂Ar), 1.93 – 1.86 (m, 2H, -CH₂). ¹³C{¹H} NMR (151 MHz, CDCl₃) δ 157.83, 134.59, 129.44, 113.85 (Ar), 55.39 (-OMe), 34.58 (-CH₂Ar), 33.55 (-CH₂). GC-MS [M]⁺ : 256.1.

1,3-bis(2-methoxyphenyl)propane (3.3c). Colourless liquid, ¹H NMR (400 MHz, CDCl₃) δ 7.23 – 7.17 (m, 2H, Ar), 6.81 – 6.72 (m, 6H, Ar), 3.80 (s, 6H, -OMe), 2.64 (t, *J* = 7.8 Hz, 4H, -CH₂Ar), 2.02 – 1.91 (m, 2H, -CH₂). ¹³C{¹H} NMR (151 MHz, CDCl₃) δ 159.82, 144.08, 129.39, 121.05, 114.41, 111.22 (Ar), 55.29 (-OMe), 35.61 (-CH₂Ar), 32.78 (-CH₂). GC-MS [M]⁺ : 256.1.

1,3-bis(3-chlorophenyl)propane (3.3d).¹⁷ Colourless liquid, ¹H NMR (400 MHz, CDCl₃) δ 7.24 – 7.13 (m, 6H, Ar), 7.05 (dt, *J* = 7.3, 1.7 Hz, 2H, Ar), 2.62 (t, *J* = 7.7 Hz, 4H, -CH₂Ar), 1.94 (p, *J* = 7.7 Hz, 2H, -CH₂). ¹³C{¹H} NMR (151 MHz, CDCl₃) δ 144.10, 134.24, 129.75, 128.67, 126.76, 126.21 (Ar), 35.10 (-CH₂Ar), 32.58 (-CH₂). GC-MS [M]⁺ : 264.0.

1,3-bis(4-chlorophenyl)propane(3.3f).^{15,17} Colourless liquid, ¹H NMR (400 MHz, CDCl₃) δ 7.26 – 7.22 (m, 4H, Ar), 7.12 – 7.06 (m, 4H, Ar), 2.62 – 2.57 (m, 4H, -CH₂Ar), 1.90 (p, *J* = 7.6 Hz, 2H, -CH₂). ¹³C{¹H} NMR (151 MHz, CDCl₃) δ 140.54, 131.68, 129.89, 128.58 (Ar), 34.71 9-CH₂Ar), 32.87 (-CH₂). GC-MS [M]⁺ : 264.0.

1,3-bis(4-fluorophenyl)propane(3.3h).^{15,17} Colourless liquid, ¹H NMR (600 MHz, CDCl₃) δ 7.15 – 7.10 (m, 4H, Ar), 6.97 (t, *J* = 8.7 Hz, 4H, Ar), 2.61 (t, *J* = 7.7 Hz, 4H, -CH₂Ar), 1.94 – 1.88 (m, 2H, -CH₂). ¹⁹F NMR (565 MHz, CDCl₃) δ -117.81. ¹³C{¹H} NMR (151 MHz, CDCl₃) δ 162.18, 160.57, 137.82, 137.80, 129.86, 129.81, 115.26, 115.12 (Ar), 34.59 (-CH₂Ar), 33.36 (-CH₂). GC-MS [M]⁺: 232.1.

1,3-bis(3-fluorophenyl)propane(3.3i). Colourless liquid, ¹H NMR (600 MHz, CDCl₃) δ 7.11 (dd, *J* = 8.4, 5.6 Hz, 4H, Ar), 6.99 – 6.93 (m, 4H, Ar), 2.60 (t, *J* = 7.7 Hz, 4H, -CH₂Ar), 1.92 – 1.87 (m, 2H, -CH₂). ¹⁹F NMR (565 MHz, CDCl₃) δ -117.83. ¹³C{¹H} NMR (151 MHz, CDCl₃) δ 160.57, 137.79, 129.86, 129.81, 115.26, 115.12 (Ar), 34.59 (-CH₂Ar), 33.36 (-CH₂). GC-MS [M]⁺: 232.1.

1,3-di-*p*-tolylpropane (3.3j).^{15,17} Colourless liquid, ¹H NMR (600 MHz, CDCl₃) δ 7.10 (d, *J* = 9.6 Hz, 8H, Ar), 2.62 (t, *J* = 7.7 Hz, 4H, -CH₂Ar), 2.33 (s, 6H), 1.97 – 1.90 (m, 2H, -CH₃Ar). ¹³C{¹H} NMR (151 MHz, CDCl₃) δ 139.41, 135.24, 129.10, 128.46 (Ar), 35.11 (-CH₂Ar), 33.29 (-CH₃Ar), 21.14 (-CH₂). GC-MS [M]⁺: 224.1.

1,3-di-*m*-tolylpropane (3.3k).¹⁵ Colourless liquid, ¹H NMR (600 MHz, CDCl₃) δ 7.20 – 7.15 (m, 2H, Ar), 7.03 – 6.97 (m, 6H, Ar), 2.62 (t, *J* = 7.8 Hz, 4H, -CH₂Ar), 2.34 (s, 6H, -CH₃Ar), 1.98 – 1.91 (m, 2H, -CH₂). ¹³C{¹H} NMR (151 MHz, CDCl₃) δ 142.44, 137.95, 129.41, 128.32, 126.58, 125.57 (Ar), 35.58 (-CH₂Ar), 33.14 (-CH₃Ar), 21.56 (-CH₂). GC-MS [M]⁺: 224.1.

1-fluoro-3-(3-phenylpropyl)benzene (3.3r). Colourless liquid (Yield 79%), ¹H NMR (600 MHz, CDCl₃) δ 7.36 – 7.33 (m, 2H, Ar), 7.30 – 7.22 (m, 5H, Ar), 7.01 (dd, *J* = 7.7, 3.9 Hz, 1H,

Ar), 6.97 – 6.93 (m, 1H, Ar), 2.74 – 2.68 (m, 4H, -CH₂Ar), 2.06 – 1.98 (m, 2H, -CH). ¹⁹F NMR (565 MHz, CDCl₃) δ -113.90. ¹³C{¹H} NMR (151 MHz, CDCl₃) δ 163.87, 162.25, 145.02, 142.42, 129.82, 129.77, 128.58, 128.56, 128.49, 128.44, 125.97, 125.87, 124.22, 124.21, 115.42, 115.28, 112.81, 112.67 (Ar), 35.57 (-CH₂Ar), 35.44 (-CH₂Ar), 35.25 (-CH₂Ar), 35.24 (CH₂Ar), 33.09 (-CH₂), 32.79 (-CH₂). GC-MS [M]⁺ : 214.1.

1-fluoro-4-(3-(4-methoxyphenyl)propyl)benzene (3.3s).^{14,15} Colourless liquid (Yield 75%), ¹H NMR (400 MHz, CDCl₃) δ 7.15 – 7.06 (m, 4H, Ar), 7.00 – 6.92 (m, 2H, Ar), 6.86 – 6.79 (m, 2H, Ar), 3.79 (s, 3H, -OMe), 2.64 – 2.54 (m, 4H, -CH₂Ar), 1.90 (p, *J* = 7.7 Hz, 2H). ¹⁹F NMR (565 MHz, CDCl₃) δ -118.00. ¹³C{¹H} NMR (151 MHz, CDCl₃) δ 162.15, 160.54, 157.90, 138.05, 134.33, 129.87, 129.82, 129.43, 115.19, 115.05, 113.90 (Ar), 55.41 (-OMe), 34.65 (-CH₂C₆H₄F)), 34.52 (-CH₂C₆H₄OMe)), 33.45 (-CH₂). GC-MS [M]⁺ : 244.1.

1-methoxy-3-(3-phenylpropyl)benzene (3.3t). Colourless liquid (Yield 85%), ¹H NMR (400 MHz, CDCl₃) δ 7.36 – 7.28 (m, 3H, Ar), 7.23 (dd, *J* = 7.5, 1.4 Hz, 3H, Ar), 6.84 – 6.81 (m, 1H, Ar), 6.80 – 6.75 (m, 2H, Ar), 3.84 (s, 3H, -OMe), 2.68 (q, *J* = 8.2 Hz, 4H, -CH₂Ar), 2.05 – 1.94 (m, 2H, -CH). ¹³C{¹H} NMR (151 MHz, CDCl₃) δ 159.76, 144.09, 142.41, 129.39, 128.59, 128.44, 125.88, 121.03, 114.36, 111.15 (Ar), 55.28 (-OMe), 35.61 (-CH₂Ph), 35.56 (-CH₂C₆H₄OMe), 32.95 (-CH₂). GC-MS [M]⁺ : 226.1.

1-methoxy-4-(3-phenylpropyl)benzene (3.3u).¹⁵ Colourless liquid (Yield 92%), ¹H NMR (600 MHz, CDCl₃) δ 7.28 (dd, *J* = 8.6, 6.5 Hz, 2H, Ar), 7.20 – 7.17 (m, 3H, Ar), 7.10 (d, *J* = 8.7 Hz, 2H, Ar), 6.83 (d, *J* = 8.7 Hz, 2H, Ar), 3.79 (s, 3H, -OMe), 2.67 – 2.58 (m, 4H, -CH₂Ar), 1.96 – 1.89 (m, 2H, -CH₂). ¹³C{¹H} NMR (151 MHz, CDCl₃) δ 157.86, 142.52, 134.52, 129.45, 128.59, 128.43, 125.84, 113.87 (Ar), 55.41 (-OMe), 35.52 (-CH₂Ph), 34.65 (-CH₂C₆H₄OMe), 33.32 (-CH₂). GC-MS [M]⁺ : 226.1.

1-fluoro-4-(3-phenylpropyl)benzene (3.3v).¹⁵ Colourless liquid (Yield 83%), ¹H NMR (600 MHz, CDCl₃) δ 7.32 (t, *J* = 7.5 Hz, 3H, Ar), 7.24 – 7.21(m, 4H, Ar), 7.18 – 7.13 (m, 1H, Ar), 7.00 (t, *J* = 8.5 Hz, 1H, Ar), 2.69 (t, *J* = 7.7 Hz, 4H, -CH₂Ar), 2.04 – 1.93 (m, 2H, -CH₂). ¹⁹F NMR (565 MHz, CDCl₃) δ -117.86. ¹³C{¹H} NMR (151 MHz, CDCl₃) δ 160.56, 142.43, 137.98, 129.82, 128.58, 128.44, 125.87, 115.21, 115.07 (Ar), 35.57 (-CH₂Ph), 34.71 (-CH₂C₆H₄F), 33.09 (-CH₂). GC-MS [M]⁺ : 214.1.

1-methoxy-2-(3-phenylpropyl)benzene (3.3w). Colourless liquid (Yield 60%), ¹H NMR (600 MHz, CDCl₃) δ 7.34 – 7.30 (m, 2H, Ar), 7.27 – 7.20 (m, 4H, Ar), 7.18 (dd, *J* = 7.4, 1.9 Hz, 1H, Ar), 6.93 (t, *J* = 6.8 Hz, 1H, Ar), 6.89 (d, *J* = 8.2 Hz, 1H, Ar), 3.86 (s, 3H, -OMe), 2.75 – 2.69 (m, 4H, -CH₂Ar), 2.01 – 1.95 (m, 2H, -CH₂). ¹³C{¹H} NMR (151 MHz, CDCl₃) δ 157.63, 142.79, 130.88, 129.93, 128.57, 128.36, 127.08, 125.74, 120.46, 110.38 (Ar), 55.37 (-OMe), 35.89 (-CH₂Ph), 31.47 (-CH₂C₆H₄OMe), 30.08 (-CH₂). GC-MS [M]⁺ : 226.1.

3.5.12. Computational details

The geometries of all the considered complexes were fully optimized using the DFT (PBE)²⁷ Method on the Gaussian-09 package.²⁸ The LANL2DZ²⁹ and 6-311G (d, p) basis set with a polarization function were used, respectively, for the metal (Ru) and non-metal atoms. The method and basis set were selected according to previous reports on pincer ruthenium complexes.^{18,20,22} The transition states were located using the synchronous transit-guided quasi Newton (QST2) Genecp (gen keyword with the effective core potential) to define the basis set. The empirical dispersion-GD₃ was used in all molecular geometry optimization and energy computations. Frequency calculations characterize the obtained stationary points as minima structures or transition states based on the number of imaginary frequencies. Single point calculations were performed to calculate the relative free energy values at 140 °C.

Supporting information (containing NMR spectra and of various compounds complexes, HRMS data, Kinetics plot, GC plot, Cartesian coordinates of the computed complexes) for chapter III is available as appendix II and can be found at

Chapter- IV

Ligand-Free Guerbet-Type Reactions in Air Catalyzed by in-situ Formed Complexes of Base Metal Salt Cobaltous Chloride

The content of this chapter has been adapted from “*Ligand-Free Guerbet-Type Reactions in Air Catalyzed by in situ Formed Complexes of Base Metal Salt Cobaltous Chloride*” by Nandi, P. G.; Kumar, P.; Kumar, A. *Catal. Sci. Technol.* **2022**, *12*, 1100-1108.

4.1. Introduction

Catalytic methods that bring about the formation of C–C bonds find wide synthetic utility and lead to valuable fuel chemicals, fine chemicals, agrochemicals, pharmaceuticals and natural products.¹ One of the most favourite routes to C–C bond forming reactions include the transition metal catalysed activation of C–X (X = H, Cl, Br and I) bonds *via* radical² or organometallic pathways (Scheme 4.1).³ Of late, there has been a dramatic surge in the exploration of methods that use alcohols as an alkylating agent. Fondly tagged as a “hydrogen borrowing strategy”, these C–C bond forming reactions are green and atom-economical as they give water as the sole by-product. While metal-free⁴ systems for the β -alkylation of alcohols lead to large amounts of waste^{4b, c} arising from the use of stoichiometric amounts of base, the use of toxic precious metals such as palladium,⁵ iridium,⁶ rhodium⁷ and ruthenium^{6b, d, j, 8} poses challenges in the economic viability of transition metal based homogeneous catalytic systems. In pursuit of earth-abundant, environmentally benign and inexpensive β -alkylation systems, researchers have developed catalysts based on cobalt,⁹ copper,^{10a, b} chromium,^{10c} manganese,¹¹ iron^{11k, l} and nickel.¹²

Scheme 4.1: Traditional approach to C-alkylation reaction.^{2,3}

Transition metal catalysed dehydrogenation of primary and secondary alcohol produces the corresponding aldehyde and ketone which in the presence of a base undergoes aldol-condensation to produce α, β unsaturated ketone with water as a sole by-product. Hydrogenation of this α, β unsaturated ketone produces the β -alkylated alcohol (Scheme 4.2).

In 2003, Shim and co-workers first demonstrated the β -alkylation of secondary alcohols with primary alcohols that is catalyzed by the phosphine based salt dichloro *tris*(triphenylphosphine)ruthenium(II) [RuCl₂(PPh₃)₃] in presence of NaOH (3 equivalents) (Scheme 4.3). This methodology afforded a variety of β -alkylated alcohol products.^{8f}

In 2017, Achard and co-workers reported NPN tridentate pyridine based ruthenium metal complex (**4.Ru1**) for the formation of α -alkylated ketones as a major product during the

condensation of primary and secondary alcohols (Scheme 4.4).^{8b} A variety of substrates could be α -alkylated using the optimised conditions.

Scheme 4.2: A new strategy towards C-alkylation using alcohol as a starting material

Scheme 4.3: $\text{RuCl}_2(\text{PPh}_3)_3$ catalyzed β -alkylation of secondary alcohols with primary alcohols.^{8f}

Scheme 4.4: The **4.Ru1** catalyzed formation of α -alkylated ketones starting from primary and secondary alcohols.^{8b}

Scheme 4.5: The **4.Ru2** catalyzed formation of β -alkylated alcohols starting from primary and secondary alcohols.^{6d}

Crabtree carried out the NNN pincer-ruthenium (**4.Ru2**) catalyzed β -alkylation of secondary alcohols with primary alcohols (Scheme 4.5).^{6d} Using the developed protocol a variety of substrates could be β -alkylated and a maximum of 95 TON was obtained.

Scheme 4.6: The **4.Ru3** catalyzed β -alkylation of secondary alcohols with primary alcohols.^{8c}

In 2016, Yu and co-workers introduced a ligand system with trifluoromethylated groups which in presence of a ruthenium salt formed complex **4.Ru3** that is active for the β -alkylation of alcohols.^{8c} The CF_3 groups present in the metal complex provides the lipophilicity, electronegativity and H-bond formation ability. In presence of **4.Ru3** as catalyst, the β -alkylated alcohols were formed from primary and secondary alcohols with excellent yield (Scheme 4.6).^{8c} The precursor Ru(III) in presence of KOH transformed to Ru(II) species which

as considered as the active species that give rise to the excellent catalytic activity towards β -alkylation.

Scheme 4.7: The **4.Ru9** catalyzed β -alkylation of secondary alcohols with primary alcohols.⁸¹

Recently, Kumar has reported the β -alkylation of 1-phenylethanol with benzyl alcohol and its derivatives catalysed by NNN pincer-Ru complexes based on *bis*(imino)pyridine and 2,6-*bis*(benzimidazole-2-yl) pyridine ligands (Scheme 4.7).⁸¹ Among all the considered catalysts, **4.Ru9** shows the best activity for the β -alkylation. Kumar has achieved highest TON of 372000 at a loading of 0.00025 mol% **4.Ru9** under solvent free conditions.⁸¹ A detailed analysis of reaction mechanism with the help of several control experiments and DFT studies led to the conclusion that β -hydride elimination is the RDS.⁸¹

Scheme 4.8: The **4.Ir1** catalyzed β -alkylation of secondary alcohols with primary alcohols.⁸⁰ Gülcemal and co-workers observed excellent activity in the β -alkylation of secondary alcohols with primary alcohols in the presence of a imidazol-2-ylidene ligand-based iridium(I) **4.Ir1**

catalyst at very low loadings (Scheme 4.8).^{8o} Up to 940000 TON was achieved in the presence of 20 mol% NaOH and 0.0001 mol% **4.Ir1** under aerobic conditions.

Scheme 4.9: The **4.Ir2** catalyzed β -alkylation of secondary alcohols with primary alcohols.¹¹ⁿ

Bera and co-workers also explored the β -alkylation of secondary alcohols with primary alcohols using an *N*-heterocyclic carbene based iridium catalyst **4.Ir2** (Scheme 4.9).¹¹ⁿ The catalytic system demonstrated very good activity towards the β -alkylation owing to the pyridyl(benzamide)-functionalized NHC backbone. The catalyst **4.Ir2** demonstrated good activity over a wide range of substrates using the optimized reaction conditions (Scheme 4.9).^{11k}

Kumar has also reported $CrCl_3 \cdot 6H_2O$ and its NNN-pincer complex **4.Cr1** as efficient catalyst for the β -alkylation secondary alcohols with primary alcohols under conventional as well as under microwave heating conditions with high yield (Scheme 4.10).^{10c} In particular, pincer-Cr complex **4.Cr1** (0.005 mol%) based on *bis*(iminopyridine) in presence of 5 mol% NaO^tBu at 140 °C provide excellent activity for β -alkylation under conventional heating (84% yield and 16800 TON at 5600 TOF⁻¹) and microwave condition (90% yield and 18000 TON at 12000 TOh⁻¹) after only 3 hours and 1.5 hours respectively. The precursor salt $CrCl_3 \cdot 6H_2O$ also exhibited very good reactivity under the same reaction conditions but resulted in comparatively lower yields than its pincer complex under both conventional (79% yield and 15800 TON at 5267 TOh⁻¹) and microwave heating (76% yield and 15200 TON at 10133 TOh⁻¹) (Scheme 4.10).^{10c}

In 2012, in a first report, Sun and co-workers carried out the catalytic β -alkylation of secondary

$R^1 = C_6H_5$, $R^2 = C_6H_5$; Yield = 90%

$R^1 = 4\text{-Me-C}_6\text{H}_4$, $R^2 = C_6H_5$; Yield = 83%

$R^1 = 4\text{-OMe-C}_6\text{H}_4$, $R^2 = C_6H_5$; Yield = 84%

$R^1 = C_6H_5$, $R^2 = 4\text{-Cl-C}_6\text{H}_4$; Yield = 91%

Scheme 4.10: The **4.Cr1** catalyzed β -alkylation of secondary alcohols with primary alcohols.^{10c}

alcohols with primary alcohols using commercially available and inexpensive ferrocenecarboxaldehyde (**4.Fe1**).^{10d} In the presence of NaOH (20 mol%) under argon medium at 130 °C in *p*-xylene, **4.Fe1** (5 mol%) catalyzed the β -alkylation of 1-phenylethanol with benzyl alcohol to produce β -alkylated product in 97% yield (Scheme 4.11).^{10d}

$R^1 = C_6H_5$, $R^2 = C_6H_5$; Yield = 97%

$R^1 = C_6H_5$, $R^2 = 4\text{-Me-C}_6\text{H}_4$; Yield = 80%

$R^1 = 4\text{-Me-C}_6\text{H}_4$, $R^2 = C_6H_5$; Yield = 82%

$R^1 = 4\text{-OMe-C}_6\text{H}_4$, $R^2 = C_6H_5$; Yield = 81%

Scheme 4.11: The **4.Fe1** catalyzed β -alkylation of secondary alcohols with primary alcohols.^{10d}

Balaraman and co-workers carried out the efficient β -alkylation of 1-phenylethanol with benzyl alcohol using $\text{NiBr}_2/\text{TMEDA}$ (1:1) (5 mol%) at 130 °C in *n*-octane in the presence of 1 equivalent KOH and obtained up to 91% yield of the β -alkylated product (Scheme 4.12).^{12f} This catalytic system is effective for a broad range of substrates and led to the corresponding β -alkylated products in good yields.

Scheme 4.12: The $\text{NiBr}_2/\text{TMEDA}$ catalyzed β -alkylation of secondary alcohols with primary alcohols.^{12f}

Scheme 4.13: The **4.Ni1** catalyzed β -alkylation of secondary alcohols with primary alcohols.^{12g}

Kumar has reported a series of pincer-Ni complexes based on *bis*(imino)pyridine ligands.^{12g} Among them, **4.Ni1** (0.005 mol%) is most active for the β -alkylation of secondary alcohols with primary alcohols which gave very high TONs of upto 18400 in the presence of 5 mol% NaO^tBu at 140 °C under air after 24h (Scheme 4.13).^{12g}

Scheme 4.14: The **4.Mn1** catalyzed β -alkylation of secondary alcohols with primary alcohols.^{11m}

Recently, Kumar and co-workers have demonstrated the β -alkylation of secondary alcohols with primary alcohols by using a series of pincer-Mn complexes based on *bis(imino)pyridine* ligands. Among them, **4.Mn1** (0.5 mol%) proved to be the best while catalyzing the β -alkylation in the presence of 2.5 mol% NaOH at 140 °C in neat conditions under both microwave as well as conventional heating to achieve 85% yield (1700 TON, 850 TOs/h) and 92% yield (1840 TON, 153 TOs/h) after 2h and 12 h respectively (Scheme 4.14).^{11m} This catalytic system could tolerate a large variety of substrates under both conventional and microwave heating.

The first report on the Co-catalyzed β -alkylation of alcohols came from the group of Kempe^{9b} using a PN₃P pincer-Co (**4.Co1**) (5 mol%) in the presence of 1.1 equivalents of KHMDS (potassium hexamethyl disilazane) as a base that gave up to 90% yield of the β -alkylated product (Scheme 4.15 and 4.18).^{9b} The complex **4.Co1** is capable for the alkylation of variety of alcohols starting from aliphatic to aromatic to hetero cyclic alcohols with moderate to good yield though the base loading is very high (1.1 equivalents KHMDS).

In 2021, Ding has reported the use of a cobalt catalyst **4.Co2** (0.7 mol%) supported by a *iPr*PPPN^HPy^{Me} tridentate ligand for the β -alkylation of alcohols in up to 80% yield at 110 °C at a very high base loading (110 mol%) (Scheme 4.16).^{9c}

Scheme 4.15: The **4.Co1** catalyzed β -alkylation of secondary alcohols with primary alcohols.^{9b}

Scheme 4.16: The **4.Co2** catalyzed β -alkylation of secondary alcohols with primary alcohols.^{9c}

The β -alkylation of a large variety of substrates were carried out with **4.Co2** (0.7 mol%) in the presence of KOtBu(110 mol%) under N₂ atmosphere at 110 °C.^{9c}

In 2010, Crabtree demonstrated the β -alkylated alcohol formation starting from primary and secondary alcohols using 1 equivalent of NaOH or KOH as base without the need of any metal salt or complex,^{10e} where, in very short time duration (4h), good to excellent yields of β -alkylated products were achieved (Scheme 4.17).^{10e}

Very recently, Gunanathan and co-workers have reported that sub stoichiometric (20 mol%) base mediated β -alkylation of secondary alcohols with primary alcohols in toluene (Scheme 4.18).^{10f} The β -alkylation of 1-phenyl alcohol with benzyl alcohol and its derivatives were

performed in presence of KOH (20 mol%) in toluene at 135 °C for 36 h to achieve very good yield of β -alkylated product.

$R^1 = C_6H_5, R^2 = C_6H_5$; Yield = 99% (neat, KOH 4h)

$R^1 = 4\text{'-Br-C}_6\text{H}_4, R^2 = C_6\text{H}_5$; Yield = 93% (neat, KOH 4h)

$R^1 = 4\text{'-Cl-C}_6\text{H}_4, R^2 = C_6\text{H}_5$; Yield = 79% (KOH, 4h)

$R^1 = 4\text{'-Cl-C}_6\text{H}_4, R^2 = C_6\text{H}_5$; Yield = 66% (NaOH, 25h)

$R^1 = C_6H_5, R^2 = 4\text{'-Cl-C}_6\text{H}_4$; Yield = 68% (KOH, 4h)

Scheme 4.18: KOH (20%) mediated β -alkylation secondary alcohols with primary alcohols.^{10e}

4.2. Objectives of the current work

A comprehensive literature survey reveals that the pincer complexes and also other metal complexes are very active for the β -alkylation of alcohols with very high base loading.

Crabtree,^{4b} Gunanathan,^{10e} Jhonson and Wendit^{10f} independently reported β -alkylation of secondary alcohols with primary alcohols mediated only by a base albeit at high loadings. On the basis of these facts, the current work attempts to address the following questions:

- Can we attempt the β -alkylation of alcohols with catalytic amount of base loading?
- Can we utilize the base metal salt instead of precious metal salt or metal complexes for the β -alkylation of alcohols?
- If yes, can we design a very good catalytic system based on base metal salts that can tolerate various functional group on alcohol molecules for β -alkylation of alcohols?
- Can we carry out the reaction in air which is easy to perform?

To the best of our knowledge there are no other reports on Co catalyzed β -alkylation of alcohols with catalytic amount of base loading. The current study reports high yields (up to 89% yield, *ca.* 8900 TON) in β -alkylation of alcohols using readily available CoCl_2 at loading as low as 0.01 mol% in the presence of relatively small amounts of NaO^tBu (2.5 mol%) (Scheme 4.19).

Scheme 4.19. Efficient cobalt-based catalysts reported for β -alkylation of 1-phenyl ethanol and benzyl alcohol.

4.3. Results and discussion

4.3.1. Studies on the cobaltous chloride catalyzed β -alkylation of 1-phenyl ethanol with benzyl alcohol

The β -alkylation studies were initiated using benzyl alcohol and 1-phenyl ethanol as a model primary and secondary alcohol, respectively (Table 4.1). The reaction carried out in the presence of cobaltous chloride (1.0 mol%) and NaO^tBu (2.5 mol%) (entry 1, Table 4.1) yielded 25% of the β -alkylated product **4.4** (ca. 25 TON) in 86% selectivity (entry 1, Table 4.1 and 4.S1). However, the yield of **4.4** dropped to 8% in the presence of mercury (entry 2, Table 4.1). Similar to the very recent report by Wang^{14b} on CoCl₂ catalyzed borylation, we found black heterogeneous Co nanoparticles (NPs) within 5 minutes of reaction (Figure 4.S91). However, in contrast to Wang's conditions, as the current reaction was performed in air, these particles were inactive and gave poor yields. Not surprisingly, repeating the reaction in an argon atmosphere under otherwise identical conditions gave better yields (ca. 44%) of **4.4** (entry 3, Table 4.1).

The rate of formation of Co NPs could be slowed down by a systematic decrease in the CoCl₂ loading while maintaining the amount of NaO^tBu at 2.5 mol% (entries 4–7, Table 4.1). One may note that as the catalyst loading was varied from 1 mol% to 0.01 mol%, the concentration of the catalyst changed from 89.4 mM to 0.894 mM. This led to identification of the best (87% yield of **4.4** at 8700 TON with 91% selectivity) catalytic system (entry 7, Table 4.1). In contrast to the results obtained with 1 mol% CoCl₂ (entries 1, 2 and 3, Table 4.1), at lower loadings (0.01 mol%) of cobaltous chloride, the yield of **4.4** was comparable (entries 7, 8 and 9, Table 4.1) when the reaction was carried out in air, Ar and also in the presence of mercury which is indicative of the absence of highly sensitive Co NPs under these conditions. The exceptional activity could actually be attributed to molecular Co catalysts that are formed *in situ* (*vide infra*).

FETEM images were recorded by drop-casting the reaction mixture solution of **4.1** (5 mmol), **4.2** (5 mmol) and NaO^tBu (2.5 mol%) containing 1 mol%, 0.5 mol% and 0.01 mol% CoCl₂ on a TEM grid (Figure 4.1). It is evident that the density of nanoparticles was higher in the reaction mixture containing 1 mol% CoCl₂ (Figures 4.1a and b) in comparison to the one containing 0.5 mol% CoCl₂ (Figures 4.1c and d). While the NPs formed with 1 mol% CoCl₂ were of larger dimensions (ca. 5–6 nm), the size of the Co NPs formed upon use of 0.5 mol% CoCl₂ was relatively smaller (ca. 2–3 nm).

Notably there was hardly any NP formation when 0.01 mol% CoCl₂ was used as demonstrated by the TEM images (Figures 4.1e and f). It is thus evident that the molecular Co species are

Table 4.1. The catalytic β -alkylation of **4.2** with **4.1** under varying conditions^a

^aReaction conditions: 5 mmol of **4.1**, 5 mmol of **4.2**, X mol% of base and Y mol% of Co catalyst at 140 °C. ^bmol % of base and catalyst is with respect to total alcohol content (**4.1**+**4.2**). ^cYield is determined from ¹H NMR using toluene as standard. ^dPerformed in the presence of excess Hg. ^ePerformed under argon atmosphere. ^fPerformed at 120 °C. ^gSelectivity of **4.4** = ((Yield of **4.4***/ Total yield (**4.3** + **4.4**)) *100).

the major contributor towards catalysis when the β -alkylation is performed with 0.01 mol%

CoCl₂. Interestingly, with 0.01 mol% CoCl₂, the formation of Co NPs is observed only after stirring for prolonged times (*ca.* 8 h, Figure 4.S89). However, by this time, the β -alkylation had almost levelled off.

Figure 4.1. FETEM images obtained by drop-casting a solution of **4.1** (5 mmol), **4.2** (5 mmol) and NaO^tBu (2.5 mol%) in the presence of (a and b) CoCl₂ (1.0 mol%), (c and d) CoCl₂ (0.5 mol%) and (e and f) CoCl₂ (0.01 mol%) immediately after mixing.

Utilization of KO^tBu, Na₂CO₃, K₂CO₃ and KOH in combination with 0.01 mol% CoCl₂ was found to yield inferior results (entries 13–16, Table 4.1). The yield of the β -alkylated alcohol **4.4** in reactions catalyzed by other Co(II) catalysts (that are typically derived from CoCl₂) was either poorer (entries 12 and 19, Table 4.1) or comparable (entry 18, Table 4.1). Using CoCl₂ as a catalyst, under the best conditions (entry 7, Table 4.1), the alkylation of several 1-phenyl ethanol derivatives with a variety of benzyl alcohols was carried out (Tables 4.2 and 4.3). Notably, the yield of the β -alkylation decreased upon the use of benzyl alcohols with electron withdrawing groups in the *para*-position (**4.4a** and **4.4g**, Table 4.2), with primary/secondary alcohols based on heterocyclic rings (**4.4d**, **4.4e**, **4.4f** and **4.4l**, Table 4.2; **4.4y**, **4.4za** and **4.4zb**, Table 4.3), primary aliphatic alcohols (**4.4n–p** and **4.4zi**, Table 4.2) and secondary aliphatic alcohols (**4.4s**, Table 4.3).

Table 4.2. The CoCl_2 catalyzed β -alkylation of 1-phenyl ethanol with various derivatives of benzyl alcohol^a

^aReaction conditions: 5 mmol of **4.1**, 5 mmol of **4.2**, 2.5 mol% of NaO^tBu and 0.01 mol% of CoCl_2 . ^bYield is determined from ^1H NMR using toluene as a standard.

4.3.2. Control experiments

The following points form the basis of the proposed mechanism of the CoCl_2 catalyzed β -alkylation of alcohols:

- (i) Higher loadings (1 mol%) of CoCl_2 lead to instant particle formation (Figure 4.S91) which are rendered inactive (entry 1, Table 4.1) by air.
- (ii) At lower (0.01 mol%) loading of CoCl_2 , the similar product profiles observed for consumption of **4.2** and formation of **4.4** as a function of time for the reactions with (blue Figure 4.2a) and without (purple legends, Figure 4.2a) hot filtration^{13b,c} suggest the involvement of molecular Co species (Figures 4.S86 and 4.S88) rather than the heterogeneous

species.

(iii) Interestingly, in both cases, the catalyst heterogenized (see SEM images, Figures 4.2c and 4.S89) when the reaction levelled off after 8 h. The onset of particle formation requires about 8 h after which the reactivity is lost.

Table 4.3. The CoCl_2 catalyzed β -alkylation of various 1-phenyl ethanol derivatives with benzyl alcohol^a

^aReaction conditions: 5 mmol of **4.1**, 5 mmol of **4.2**, 2.5 mol% of NaO^tBu and 0.01 mol% of CoCl_2 . ^bYield is determined from ^1H NMR using toluene as a standard.

(iv) The decrease in productivity as we move from an interval-free reaction (Figure 4.2a, purple legend) to reactions with a three-hour break after 3 h of reaction (Figure 4.2a, brown legends) further fortifies the contribution of molecular species rather than the heterogeneous species. A three-hour break after 3 h of reaction would mean a residence time of six hours for the catalyst in the solution. By this time the reaction mixture would be ready to witness the onset of formation of Co NPs. Hence further make-up for the lost heating time does not lead to the same productivity as interval-free heating owing to the fact that the majority of the active molecular Co species are lost as Co NPs.

With an objective of elucidating the mechanism of the reaction, **4.1** (5 mmol) and **4.2** (5 mmol) were independently heated at 140 °C with CoCl₂ (0.01 mol%) and NaO^tBu (2.5 mol%) under non-inert conditions for 1 h. While analysis of the head-space indicated the formation of hydrogen (Figures 4.7 and 4.S69), the corresponding analysis of the reaction mixture indicated the formation of trace amounts of benzaldehyde and acetophenone respectively (Figures 4.S40 and 4.S41). In another experiment, a mixture of **4.1** (5 mmol) and **4.2** (5 mmol) was heated at 140 °C in the presence of CoCl₂ (0.1 mol%) and NaO^tBu (2.5 mol%) in air. The brown reaction mixture was followed with time by ESR (Figure 4.S63) and HRMS (Figure 4.3) analysis. The HRMS analysis at t = 0 h (prior to heating) showed a peak at m/z = 351.2727 and m/z = 679.5467 that corresponds to molecular complexes **4.5a** and **4.5b**, respectively, arising from the *in-situ* complex formation of **4.1** and/or **4.2** with CoCl₂.

Upon heating, the reaction mixture had a statistical mixture of various Co(II) complexes (**4.19a–4.c**) (Figures 4.3b and 4.S45) that could be attributed to coordination of starting materials and products (**4.1–4.4**) from the reaction mixture with CoCl₂. These observations clearly indicate the involvement of molecular Co(II) species during catalysis with 0.01 mol% CoCl₂ in line with the observations made in Figure 4.2. All throughout, the reaction mixture was ESR silent (Figures 4.S64–4.S68) indicative of the fact that these Co(II) species **4.5** and **4.19** are in an octahedral environment.¹⁴ One could envisage that while species **4.5a** could complete its octahedral environment by incorporation of a Cl⁻ ligand, species **4.19a** and **4.19b** can include neutral alcohol/solvent molecules to satisfy their coordination.

On the other hand, in the HRMS analysis of the reaction mixture at a higher loading of CoCl₂ (1 mol%), the only molecular species that was discernible was the one observed at m/z = 679.5034 which corresponds to **4.5b** (Figures 4.4a and 4.S55). The rest of the species could

Figure 4.2. (a) Effect of hot-filtration on the CoCl_2 (0.01 mol%) catalysed β -alkylation of **4.2** with **4.1**. (b) Typical reddish-brown clear solution observed during initial times (0–8 h) of the CoCl_2 (0.01 mol%) catalysed β -alkylation of **4.2** with **4.1**. (c) SEM image of the black Co NPs formed in the CoCl_2 (0.01 mol%) catalyzed β -alkylation of **4.2** with **4.1**.

Figure 4.3. HRMS analysis of a mixture of **4.1** (5 mmol) and **4.2** (5 mmol) in the presence of CoCl_2 (0.1 mol%) and NaO^tBu (2.5 mol%) after (a) 0 h and (b) 1 h.

be mapped to Co NPs (**4.5g**, Figures 4.4a and 4.S55–4.S62) or their precursors (**4.5d**, **4.5e**, **5h** and **4.5i**, Figures 4.4 and 4.S55–4.S62). Notably, NPs **4.5g–4.5i** are not detected by HRMS after 1 h (Figure 4.4b) of reaction owing to the fact that these species grow with time and are effectively removed by the pre-filtration (through 0.2 μm filter paper) process during mass sampling. These observations fortify our argument of rapid formation of Co NPs at a higher loading of CoCl_2 . Furthermore, one must note that species **4.5g–4.5i** are not observed during the time frame (up to 8 h) when good reactivity is observed in the CoCl_2 (0.1 mol%) catalysed β -alkylation of **4.2** with **4.1**. This is indicative of the fact that NPs that were capable of escaping the pre-filtration were not present and have not contributed to the reactivity observed in entry 7, Table 4.1.

Valuable information was obtained from deuterium labelling experiments. Heating a mixture of **4.2** (5 mmol) and **4.1a** (5 mmol) at 140 $^\circ\text{C}$ with CoCl_2 (0.01 mol%) and NaO^tBu (2.5 mol%) in open air provided **4.4a** in 43% yield (Figure 4.5). In comparison, the corresponding yield obtained from **4.1** under similar conditions is 87%.

Figure 4.4. HRMS analysis of a mixture of **4.1** (5 mmol) and **4.2** (5 mmol) in the presence of CoCl_2 (1.0 mol%) and NaO^tBu (2.5 mol%) after (a) 0 h and (b) 1 h.

Figure 4.5. NMR (^1H and ^2H) analysis of a mixture of **4.1** (5 mmol) and **4.2a** (5 mmol) in the presence of CoCl_2 (0.01 mol%) and NaO^tBu (2.5 mol%).

Analysis of the ^1H and ^2H NMR of the reaction mixture containing **4.4a** indicated C_a , C_b and C_c to be 49%, 7% and 33% deuterated, respectively. The deuterium content (88%) of **4.1a** was comparable to the net deuterium incorporated (89%) in the product **4.4a**. The ratio of deuterium incorporation at position “a” to the corresponding incorporation at position “c” was found to be 2.97 and 2.98 by ^1H and ^2H NMR, respectively. On the other hand, the reaction of a mixture of **4.2** (5 mmol), **4.1** (2.5 mmol) and **4.1a** (2.5 mmol) at 140 °C with CoCl_2 (0.01 mol%) and NaO^tBu (2.5 mol%) in open air provided **4.4a** in 63% yield (Scheme 4.20) with a KIE of 1.61.^{11k,15} These studies provide key evidence for the involvement of C–H activation (*vide infra*) in the β -alkylation of 1-phenyl ethanol with benzyl alcohol.¹¹ⁱ

4.3.3. Plausible mechanism

The results obtained from filtration experiments, GC analysis of intermediates, ESR and HRMS studies form the basis of the proposed mechanism (Schemes 4.21–4.23). When CoCl_2 is dissolved in a mixture of **4.1** and **4.2**, it spontaneously forms an octahedral complex **4.5/5.6** (Scheme 4.21). A β -hydride elimination *via* transition state (TS) **4.7/4.8** gives the corresponding carbonyl compounds **1'/2'** and the hydride complex **4.12** (Scheme 4.21). While **4.1'** and **4.2'** are detected by NMR in the independent dehydrogenation of **4.1** and **4.2**

respectively (Figures 4.S40 and 4.S41), only **4.2'** is detected by NMR in the Guerbet reaction mixture (Figures 4.S70–4.S87). Subsequent σ -bond metathesis of the O–H bond in **4.1/4.2** with Co–H of **4.12** regenerates **4.5/4.6** (Scheme 4.21) with the evolution of H₂ (detected by GC, Figure 4.7 and 4.S69).

Scheme 4.20. KIE determination via competitive labelling.

The base mediated reaction of benzaldehyde (**4.1'**) with acetophenone (**4.2'**) results in the formation of the α , β -unsaturated ketone **4.3'** (not observed in ¹H NMR but detected in a few HRMS analyses, Figure 4.S49, 4.S52 and 4.S54). The next step (Scheme 4.22) involves the insertion of the double bond of **4.3'** into the Co–H bond in **4.12** to yield **4.14** via **TS 4.13**. The cycle is completed by the σ -bond metathesis of the Co–C bond in **4.14** with the H₂ or the O–H bond of **4.1/4.2** to yield the corresponding ketone **4.3** with the regeneration of catalytically active **4.12/4.5/4.6** (Scheme 4.22). One could envisage a similar cycle for the transformation of **4.3** to **4.4** (Scheme 4.5). The loss of deuterium (*ca.* 39%) at C_a and the very low deuterium content on C_b (Figure 4.5) indicate the involvement of the dehydrogenation step **4.5** → **4.12** and a rapid equilibrium of the σ -bond metathesis step **4.12** ↔ **4.5/4.6** (Scheme 4.21). For instance, dehydrogenation of **4.1a** would result in formation of Co–D species **4.12a**. The HD that is released via σ -bond metathesis step **4.12a** → **4.5/4.6** can result in D scrambling while reacting back in the reverse direction to give a Co–H species **4.12** and the corresponding alcohol that is deuterated at O. This O–D upon σ -bond metathesis with **4.14** would transfer the deuterium back to C_a. Insertion of **4.3'** into **4.12** would lead to no deuterium incorporation at C_b.

Similar to earlier reports with Ru⁸¹ and Ir^{6h} catalysts, there is no initial build-up of **4.3** at very low loadings of CoCl₂ (Figures 4.S70 and 4.S71). This indicates rapid formation of **4.3** and **4.4** with a rate-determining dehydrogenation of either **4.1** or **4.2**. While we do not observe benzaldehyde **4.1'**, trace amounts (1–2%) of acetophenone **4.2'** are observed in the ¹H NMR of

Scheme 4.21. Dehydrogenation segment of the proposed catalytic cycle for the cobaltous chloride catalyzed β -alkylation of 4.2 with 4.1.

Scheme 4.22. Hydrogenolysis/alcoholysis of 4.3' in the proposed catalytic cycle for the cobaltous chloride catalyzed β -alkylation of 4.2 with 4.1.

the β -alkylation reaction mixture (Figures 4.S70–4.S87). Hence, it is likely that, very similar to our previous report,⁸¹ the step **4.6** \rightarrow **4.12** is rate-determining.

Scheme 4.23. Hydrogenolysis/alcoholysis of **4.3** in the proposed catalytic cycle for the cobaltous chloride catalyzed β -alkylation of **4.2** with **4.1**.

The observed KIE of 1.61 is also consistent with this argument. This means that **4.2'** has enough time to react back with Co–D species **4.12a** in a reversible fashion which eventually would reflect in the deuterium content at C_c. Hence, the deuterium distribution clearly indicates that the Co–D **4.12a** species formed in the first step is mostly transformed to a Co–H **4.12** species via a facile reverse reaction with HD and **4.2'**. Alternatively, the insertion of **4.3** into the Co–D species **4.12a** can also conveniently explain the deuterium incorporation at C_c. Further in such a case, the deuterium distribution at C_a and C_b can also be rationalized if one invokes the possibility of Co–D species **4.12a** doing a D– transfer to the β -carbon of **4.3'**. through the step **14.2a** \rightarrow **4.14a** (rather than the α -carbon as shown in the step **4.12** \rightarrow **4.14**, Scheme 4.22) and

a subsequent σ -bond metathesis with O–H of the alcohol (Scheme 4.24). However, this possibility can be ruled out owing to steric reasons.

Scheme 4.24. An alternate path for hydrogenolysis/alcoholysis of **4.3'**.

4.3.4. Kinetic studies

The time course profiles of the cobaltous chloride catalysed β -alkylation of **4.2** with **4.1** at various concentrations of catalyst, base and alcohol are shown in Figures 4.S70–4.S82c. For each reaction, the concentration of a given compound was varied while keeping all other concentrations unchanged. For kinetic reactions involving alcohol (**4.1** or **4.2**) variations, mesitylene was used as a make-up solvent. It is evident from Table 4.1 (entries 7, 8 and 9), Figures 4.2 and 4.3 that the cobaltous chloride catalyzed β -alkylation of **4.2** with **4.1** is mostly homogeneous at low catalyst loadings. Accordingly, for a range of low catalyst concentrations (<0.025 mol% CoCl₂ equivalent to <2.24 mM), we have compiled the kinetic data using the initial rate method. The plots of initial rate vs. [CoCl₂] and initial rate vs. [NaO^tBu] were linear with a negligible intercept (Figure 4.6a and b). This points to a first order dependence of the rate on the concentration of both CoCl₂ and NaO^tBu. On the other hand, the dependence on concentration of both **4.1** and **4.2** was nonlinear (Figure 4.6c and d).

Figure 4.6. Dependence of the initial rate of the Guerbet reaction on the concentration of (a) cobaltous chloride (extracted from 30 minutes data of Figures 4.S70, 4.S71, 4.S72, 4.S75a, 4.S75b and 4.S75c), (b) Sodium *t*-butoxide (extracted from 60 minutes data of Figure 4.S70, 4.S76, 4.S77, 4.S78a and 4.S78b), (c) Benzyl alcohol (extracted from 60 minutes data of Figures 4.S70, 4.S79, 4.S80, 4.S80a, 4.S80b and 4.S80c) and (d) 1-Phenyl ethanol (extracted from 60 minutes data of Figures 4.S70, 4.S81, 4.S82, 4.S82a, 4.S82b and 4.S82c) (see Figure 4.11).

4.4. Conclusion

For the first time, we report the use of readily available CoCl_2 that forms complexes with alcohols *in-situ* which efficiently catalyzes the β -alkylation of alcohols in air. Higher loading of CoCl_2 (1 mol%) is accompanied with rapid formation of heterogeneous cobalt NPs which being sensitive to air result in poor yields (25%) of β -alkylated products. A better control over

reactivity (87% yield, *ca.* 8700 TON) could be obtained by delaying the heterogenization upon operating at very small amounts of CoCl_2 (0.01 mol%). Deuterium labelling studies are indicative of the involvement of C–H activation in the cobaltous chloride catalyzed β -alkylation with a $k_{\text{H}}/k_{\text{D}}$ value of 1.61. The reaction exhibits a first-order dependence of the initial rate on the concentration of both cobaltous chloride and sodium *t*-butoxide. On the other hand, a non-linear dependence of the rate on the concentration of 1-phenyl ethanol and benzyl alcohol was observed. Molecular Co catalysts rather than heterogeneous Co NPs thus lead to superior reactivity owing to the reaction conditions. These studies could open up several related reactivity with substrates that are capable of forming *in-situ* complexes with CoCl_2 .

Figure 4.7. Evidence for H_2 evolution in the dehydrogenation of benzyl alcohol (**4.1**) catalyzed by CoCl_2 (0.01 mol %) at 140 °C *via* GC analysis.

4.5. Experimental section

4.5.1. General procedure and materials

All manipulations were carried out in air. The Co metal salts, NaO^tBu , KO^tBu , NaOH , KOH , Na_2CO_3 , K_2CO_3 , CDCl_3 , benzyl alcohol, 1-phenyl ethanol and their derivatives were purchased

either from MERCK or Sigma–Aldrich and used as such. To prepare the stock solution, CoCl_2 was dissolved either in benzyl alcohol or 1-phenyl ethanol. All catalytic reactions were carried out in air using oven-dried glassware. The 1-phenyl ethanol derivatives which were commercially not available were prepared according to literature procedure.

4.5.2. Physical measurements

^1H , $^{13}\text{C}\{\text{H}\}$ and ^{19}F NMR were recorded on a Bruker ASCEND 600 operating at 600 MHz for ^1H , 150 MHz for $^{13}\text{C}\{\text{H}\}$ or on a Bruker AVANCE 400 operating at 400 MHz for ^1H , 100 MHz for $^{13}\text{C}\{\text{H}\}$ or on a Bruker AVANCE 500 operating at 500 MHz for ^1H , 125 MHz for $^{13}\text{C}\{\text{H}\}$. Chemical shifts (δ) are reported in ppm. HRMS measurements were done using an Agilent Accurate-Mass Q-TOF ESI–MS 6520. The X-band EPR spectra were recorded on a JES-FA200 ESR spectrometer. The field-emission scanning electron microscopy (FESEM) were performed using JSM-7610F instrument. Transmission electron microscopy (TEM) analysis were carried out using a JEOL JEM-2100F FETEM instrument. GC analysis (TCD detection) was performed on a Agilent 7820-GC instrument fitted with Agilent Front SSZ Inlet N_2 HP-PLOT Q column (30 m length x 530 μm x 40 μm) using the following method: Agilent 7820-GC back detector TCD, Oven temperature: 50 $^\circ\text{C}$, Inlet temperature: 100 $^\circ\text{C}$, Detector temperature (TCD): 250 $^\circ\text{C}$, Detector, temperature (FID): 300 $^\circ\text{C}$, Time at starting temp: 0 min, Hold time = 10 min, Flow rate (carrier): 25 mL/min (N_2), Split flow: 50 mL/min, Split ratio: 10.

4.5.3. General procedure for CoCl_2 catalyzed β -alkylation of alcohols

In a 10 mL pear-shaped flask, 1-phenyl ethanol or benzyl alcohol were taken in air. This was followed by addition of 2.5 mol % of NaO^tBu and 0.01 mol % of CoCl_2 (from a stock solution either in 1-phenyl ethanol or benzyl alcohol). After the addition, the reaction mixture contained 0.61 mL (5.00 mmol) of 1-phenyl ethanol, 0.52 mL (5.00 mmol) of benzyl alcohol, 24 mg (0.25 mmol) of NaO^tBu and 0.13 mg (1 μmol) of CoCl_2 . The mixture was heated at 140 $^\circ\text{C}$ for 24 h in air. The reaction mixture was then cooled to room temperature. An aliquot (Typically 10 mg) was withdrawn from reaction mixture and the yield was determined by ^1H NMR using CDCl_3 as solvent and toluene (Typically 10 μL) as a standard.

4.5.4. Preparation of FESEM sample

An aliquot (approximately 10 mg) was withdrawn from reaction mixture and drop casted on a

glass slide. The drop casted sample was submitted for FESEM analysis. A JSM-7610F instrument was used for the field-emission scanning electron microscopy (FESEM) analysis.

4.5.5. Preparation of TEM sample

An aliquot (approximately 10 mg) was withdrawn from reaction mixture and drop casted on a TEM grid. The dropcasted sample was submitted for TEM analysis. Transmission electron microscopy (TEM) analysis were carried out using a JEOL JEM-2100F FETEM instrument.

4.5.6. General procedure for CoCl₂ catalyzed β -alkylation of alcohols-kinetic study

In a 10 mL pear-shaped flask, 1-phenyl ethanol or benzyl alcohol were taken in air. This was followed by addition of 2.5 mol % of NaO^tBu and 0.01 mol % of CoCl₂ (from a stock solution either in 1-phenyl ethanol or benzyl alcohol). After the addition, the reaction mixture contained 0.61 mL (5.00 mmol) of 1-phenyl ethanol, 0.52 mL (5.00 mmol) of benzyl alcohol, 24 mg (0.25 mmol) of NaO^tBu and 0.13 mg (1 μ mol) of CoCl₂. The mixture was heated at 140 °C and aliquots were withdrawn at periodic intervals of 0.5h, 1h, 2h, 3h, 5h, 6h, 9h, 12h, 15h, 18h, 21h and 24 h. Yield of the desired product was determined by ¹H NMR using CDCl₃ as solvent and toluene as standard.

4.5.7. Procedure for CoCl₂ catalyzed β -alkylation of alcohols with hot filtration

In a 10 mL pear-shaped flask, 1-phenyl ethanol or benzyl alcohol were taken in air. This was followed by addition of 5 mol % of NaO^tBu and 0.02 mol % of CoCl₂ (from a stock solution either in 1-phenyl ethanol or benzyl alcohol). After the addition, the reaction mixture contained 0.61 mL (5.00 mmol) of 1-phenyl ethanol, 0.52 mL (5.00 mmol) of benzyl alcohol, 24 mg (0.25 mmol) of NaO^tBu and 0.13 mg (1 μ mol) of CoCl₂. The mixture was heated at 140 °C and an aliquot was withdrawn after 1h and the yield of the desired product was determined by ¹H NMR using CDCl₃ as solvent and toluene as standard. The hot reaction mixture was subsequently filtered using 0.2 μ m Nylon Membrane Filter. The filtrate was then heated at 140 °C and aliquots were withdrawn at periodic intervals of 0.5h, 1h, 2h, 3h, 5h, 6h, 9h, 12h, 15h, 18h, 21h and 24 h. Yield of the desired product was determined by ¹H NMR using CDCl₃ as solvent and toluene as standard.

4.5.8. Procedure for CoCl₂ catalyzed β -alkylation of alcohols with 3h interval after 3h of reaction

In a 10 mL pear-shaped flask, 1-phenyl ethanol or benzyl alcohol were taken in air. This was followed by addition of 5 mol % of NaO^tBu and 0.02 mol % of CoCl₂ (from a stock solution either in 1-phenyl ethanol or benzyl alcohol). After the addition, the reaction mixture contained 0.61 mL (5.00 mmol) of 1-phenyl ethanol, 0.52 mL (5.00 mmol) of benzyl alcohol, 24 mg (0.25 mmol) of NaO^tBu and 0.13 mg (1 μmol) of CoCl₂. The mixture was heated at 140 °C and aliquots were withdrawn after 1h, 2h and 3h. The reaction mixture was then allowed to stand for 3h. After this 3h break, heating was then resumed and aliquots were withdrawn at periodic intervals of 5h, 6h, 9h, 12h, 15h, 18h, 21h and 24 h of reaction at 140 °C. Yield of the desired product was determined by ¹H NMR using CDCl₃ as solvent and toluene as standard.

Supporting information (containing NMR spectra and of reaction mixtures, HRMS data, Kinetics plot, GC plot, EPR data, TEM image, SEM image) for chapter IV is available as appendix III and can be found at

Chapter- V

Pincer-Cobalt Catalyzed Guerbet-Type β -alkylation of Alcohols in Air under Microwave Conditions

The contents of this chapter have been adapted from “*Pincer-Cobalt Catalyzed Guerbet-Type β -alkylation of Alcohols in Air under Microwave Conditions*” by Nandi, P. G.; Thombare, P.; Prathapa, S. J; Kumar, A. *Organometallics* **2022**, *41*, 22, 3387–3398.

5.1. Introduction

Methods that create C–C bonds provide convenient and versatile routes to agrochemicals, pharmaceuticals, natural products, fuels, and fine chemicals.¹ Radical² and organometallic³ pathways have largely contributed to C–C bond-forming reactions mainly via the transition-metal-catalyzed activation of C–X (X = H, Cl, Br, I) bonds. Recent years have witnessed the rise of several methods that use alcohols as an alkylating agent. These “hydrogen borrowing strategies” have continued to garner greater research interest due to their green and atom-economical nature with water as the only by-product. The use of stoichiometric amounts of base leads to large amounts of waste^{4b,c} and renders the metal-free⁴ systems inappropriate for the β -alkylation of alcohols. In a similar vein, several challenges are associated with the use of homogeneous catalytic systems based on toxic precious metals such as palladium,⁵ iridium,⁶ rhodium,⁷ and ruthenium.^{6b,d,j,8} Earth-abundant, environmentally benign, and inexpensive β -alkylation catalytic systems have been an area of intense research lately, which have rightly led to catalysts based on cobalt,⁹ copper,¹⁰ manganese,¹¹ iron,^{11k,l} nickel,¹² and chromium.¹³

Scheme 5.1: The **5.Co1** catalyzed β -alkylation of secondary alcohols with primary alcohols.^{9b}

The first report on Co-catalyzed β -alkylation of alcohols came from the group of Kempe^{9b} using a PN_3P pincer-Co (**5.Co1**) (5 mol%) in the presence of 1.1 equivalents of KHMDS (potassium hexamethyl disilazane) as a base with up to 90% yield of the β -alkylated product (Scheme 5.1).^{9b} The complex **5.Co1** is capable for the alkylation of variety of alcohols starting from aliphatic to aromatic to hetero cyclic alcohols with moderate to good yields however, at a very high base loading (1.1 equivalents of KHMDS).

In 2021, Ding has reported the use of a Co catalyst (0.7 mol%) supported by a iPr PPN $^{H}Py^{Me}$ tridentate ligand for the β -alkylation of alcohols in up to 80% yield at 110 °C at a very high base loading (110 mol%) (Scheme 5.2).^{9c} A large variety of substrates could be β -alkylated with **5.Co2** (0.7 mol%) in the presence of KO t Bu (110 mol%) under N₂ atmosphere at 110 °C.^{9c}

Scheme 5.2: The **5.Co2** catalyzed β -alkylation of secondary alcohols with primary alcohols.^{9c}

Scheme 5.3: CoCl₂ catalyzed β -alkylation of secondary alcohols with primary alcohols.^{9c}

We recently reported that cobaltous chloride (0.01 mol %) efficiently accomplishes the catalytic β -alkylation of alcohols with high yields (up to 87%) and unprecedented turnovers (ca. 8700) in the presence of only 2.5 mol % of NaO t Bu (Scheme 5.3).^{9f} This reaction has been discussed in detail in the previous chapter.

5.2. Objectives of the current work

A comprehensive literature survey reveals that the pincer complexes and also other metal complexes are very active for β -alkylation of alcohols at a very high base loading. Crabtree,^{10e} Gunanathan,^{10f} Jhonson and Wendit^{10g} have independently reported that only base can mediate the β -alkylation of secondary alcohols with primary alcohols albeit at very high loadings. In the Chapter-IV, we have demonstrated that base metal salt CoCl_2 itself acts as a very active catalyst for the β -alkylation of various secondary alcohols with primary alcohols (also see Scheme 5.3) in the presence of NaO^tBu at loadings as low as 2.5 mol% in air at 140 °C. A comprehensive literature survey reveals that the pincer complexes are very much active for the activation of alcohols molecules. Following the success in the synthesis of a series of NNN pincer-ruthenium complexes (**2.6a–d**, Figure 5.2, **Chapter-II**) based on *bis(imino)pyridine* ligands and their application as efficient catalysts for the β -alkylation of alcohols,⁸¹ the current work attempts to address the following questions:

- Using the same *bis(imino)pyridine* ligand system, can we utilize pincer-cobalt complexes rather than pincer-ruthenium complexes as catalysts for the very important β -alkylation reactions?
- How does the β -alkylation activity of pincer-cobalt complexes compare with corresponding activity of the precursor CoCl_2 ?
- What will be the functional group tolerance of the resulting β -alkylation catalytic system based on pincer-cobalt?
- Can we carry out the reaction in air which facilitates the ease of operation without compromise on the overall performance?

Apart from the studies by Kempe,^{9b} Ding^{9c} and Kumar^{9f} (Scheme 5.4), there have been no other reports on Co-based β -alkylation systems, to the best of our knowledge. In the current study, we report the synthesis of a series of NNN pincer-Co complexes based on *bis(imino)pyridine* ligands to yield complexes of the type $(\text{R}^2\text{NNN})\text{CoCl}_2$ (**5.1a**, R = ^{*i*}Pr; **5.1b**, R = ^{*t*}Bu; **5.1c**, R = Cy; **5.1d**, R = Ph; **5.1e**, R = *p*-F-C₆H₄) (Figure 5.1). While cobaltous chloride at a 0.0025 mol % loading in the presence of 2.5 mol % of NaO^tBu at 140 °C gives about a 66% yield in the β -alkylation of 1-phenylethanol with benzyl alcohol, its corresponding pincer complex

(*i*Pr²NNN)CoCl₂ (0.0025 mol %) is highly productive (ca. 1.3-fold vs CoCl₂) and results in up to 85% yield (ca. 34000 TON) of the β -alkylation product under otherwise identical conditions (Scheme 5.4).

Figure 5.1. Magnetic moment of pincer-cobalt complexes investigated in the current study for the β -alkylation of 1-phenylethanol with benzyl alcohol

Scheme 5.4. Efficient cobalt-based catalysts reported for the β -alkylation of alcohols.

5.3. Results and discussions

5.3.1. Synthesis and characterization of pincer-cobalt complexes based on bis(imino)pyridine ligands

The NNN pincer-Co complexes **5.1a–e** were synthesized in good yields by the treatment of the corresponding ligands¹⁴ with CoCl₂ in THF at room temperature for 20 h, followed by washing with diethyl ether (Scheme 5.5). The NNN pincer-Co complexes **5.1a–e** were paramagnetic in nature, as indicated by their magnetic susceptibility measurements (**5.1a**, $\mu_{\text{eff}} = 3.23 \mu_{\text{B}}$; **5.1b**, $\mu_{\text{eff}} = 4.42 \mu_{\text{B}}$; **5.1c**, $\mu_{\text{eff}} = 3.51 \mu_{\text{B}}$; **5.1d**, $\mu_{\text{eff}} = 4.09 \mu_{\text{B}}$; **5.1e**, $\mu_{\text{eff}} = 4.19 \mu_{\text{B}}$).¹⁵ The paramagnetic behavior of the considered complexes was further confirmed by an EPR analysis (Figure 5.2).¹⁶

All of the considered complexes other than **5.1d**^{14c} are new and have not been reported. In contrast to Jiang's report^{14c} on the structure of **5.1d**, which contained two molecules per asymmetric unit, the single-crystal X-ray analysis of **5.1d** in the current study shows only one molecule in the asymmetric unit with Co in a trigonal-bipyramidal environment having the pincer ligand bound in a meridional fashion with the two chlorides *cis* to each other. Very similar to our studies with pincer-Ni complexes^{12g} and pincer-Fe complexes,^{12h} the dicationic octahedral complex [(^{R2}NNN)₂Co]²⁺ in **5.3c** whose charge is balanced by a dianionic tetrahedral cobalt tetrachloride is obtained during crystallization upon layering a solution of **5.1c** in methanol with hexane (Scheme 5.2). This presumably arises due to the equilibration of **5.1c** with **5.3c** in the mother liquor (Scheme 5.5). In **5.3c**, which has two molecules per asymmetric unit, the two pincer ligands are attached in a meridional fashion to the Co, which is in an octahedral environment (Scheme 5.5). While the complex (^{Ph2}NNN)CoCl₂ (**5.1d**) crystallized in P21/n space group, the complex [(^{Cy2}NNN)₂Co][CoCl₄] (**5.3c**) crystallized in the I $\bar{4}$ space group (Table 5.1 and Table 5.S1). The Co–N(pyridyl) bond distance is slightly elongated in the case of neutral complex **5.1d**, 2.011(10) Å; **5.3c**, 1.972(8) and 1.968(7) Å). In **5.1d**, one of the Co–N(imine) bonds was longer (2.287(11) Å) than the other (2.260(10) Å) with (pyridyl)N–Co–N(imine) bond angles of 74.7(4) and 76.20(4)° respectively (Table 5.2 and Table 5.S2).

Similarly, each of the pincer fragments in **5.3c** had one long Co–N(imine) bond (2.190(9) and 2.194(10) Å) and one short Co–N(imine) bond (2.149(8) and 2.163(8) Å). The corresponding (pyridyl)N–Co–N(imine) bond angles were also larger (77.40(4) and 76.40(3)°) and smaller (75.30(4) and 76.10(4)°), respectively. The N(imine)–(pyridyl)N–N(imine) bond angle in the

case of **5.1d** (113.83°) is slightly larger than the corresponding angles in **5.3c** (110.88 and 110.91°).

Scheme 5.5. General synthetic pathway towards (R²NNN)CoCl₂ (**5.1a-e**)^a

^aThe molecular structures of **5.1d** and **5.3c** are provided as ORTEP figures drawn at 40% probability. The cyclohexyl groups on two N atoms of one of the pincer fragments in **5.3c** and all of the hydrogen atoms on both **5.1d** and **5.3c** are omitted for the sake of clarity.

Figure 5.2. EPR spectra of pincer-Co complexes **5.1a-e** in methanol at 77 K.

X-ray diffraction studies, HRMS analysis provided key evidence for the presence of fragments originating from both **5.1** and **5.3** (Figure 5.3). For example, the HRMS analysis of **5.1a** showed peaks at *m/z* values of 246.6250, 311.0593, 406.1107 and 469.1891 that correspond to [**5.3a** - CoCl₄]²⁺, [**5.1a** - Cl]⁺, [**5.1a** - Cl + CH₃CN + 3H₂O]⁺, and [**5.1a'** + 2CH₃CN + 3H₂O + Na]⁺, respectively. HRMS analyses were thus complementary to single-crystal X-ray diffraction studies, clearly indicating that in solution complex **5.1** exists in equilibrium with **5.3** (Scheme 5.5), the position of which is dictated by the nature of the R group (R = ⁱPr, ^tBu, Cy, Ph, *p*-F-C₆H₄).

The TGA analysis demonstrated the excellent thermal stability of the synthesized NNN pincer-Co complexes **5.1a-e/5.3a-e** (Figure 5.4). Due to the lack of labile ancillary ligands, hardly any mass loss was observed at lower temperatures and a sudden decomposition was observed at elevated temperatures (Figure 5.4). However, prior to decomposition, **5.1a** and **5.1c** demonstrated gradual mass losses of about 11% and 10%, respectively, that correspond to the loss of one chloride.^{12g}

5.3.2. Studies on the 5.1-catalyzed β -alkylation of 1-phenyl-ethanol with benzyl alcohol

Employing benzyl alcohol and 1-phenylethanol as model primary and secondary alcohol, respectively, the studies on β -alkylation at 140 °C were initiated using **5.1a** as the catalyst (Table 5.3). In the presence of **5.1a** (0.01 mol %) and NaO^tBu (5 mol %) (entry 1, Table 5.3) about 87% of the β -alkylated product **5.7** (ca. 8700 TON) was obtained in 96% selectivity (Table 5.3). The yield of **5.7** was comparable when the reaction was carried out at a lower loading of NaO^tBu (2.5 mol %) (entry 2, Table 5.3).

Figure 5.3. HRMS analysis of **5.1a** in acetonitrile and methanol.

Figure 5.4. TGA analysis of pincer-Co complexes **5.1a–e** under argon with a heating rate of 10 °C min⁻¹.

Though this reactivity is seemingly comparable with the results obtained by us recently with CoCl_2 as catalyst (0.01 mol %) (entry 2 vs entry 3, Table 5.3),^{9f} one can appreciate the value of **5.1a** as a more efficient catalyst, as is evident from further optimizations. Lowering of the base loading (1.25 mol % NaO^tBu) resulted in poorer yields (entry 4, Table 5.3). Hence, further studies were carried out at a catalyst and base loadings of 0.01 and 2.5 mol %, respectively. The β -alkylation did not occur upon use of Na_2CO_3 and K_2CO_3 (entries 5 and 6, Table 5.3). While KOH demonstrated poor reactivity (entry 7, Table 5.3) in the **5.1a**-catalyzed β -alkylation, good yields were obtained in the corresponding reaction with NaOH (entry 8, Table 5.3). In the **5.1a**-catalyzed reaction, among NaO^tBu (2.5 mol %) (entry 2, Table 5.3) and KO^tBu (entry 9, Table 5.3), the yield of **5.7** in the case of the former was better than that of the latter. Among the catalysts considered (entry 2 and entries 10-13, Table 5.3), the yield of β -alkylated product was very good with **5.1a** (88% yield at 8800 TON, entry 2, Table 5.3) and **5.1e** (83% yield at 8300 TON, entry 13, Table 5.3). The yields of **5.7** hardly changed (84%, ca. 16800 TON) when the loading of both **5.1a** and **5.1e** was decreased to 0.005 mol % (entries 14 and 15, Table 5.3). However, since **5.1e** had poor solubility, further optimization was carried out only with **5.1a**. Upon a further decrease in the amount of **5.1a** to 0.0025 mol %, the β -alkylation in the presence of NaO^tBu (2.5 mol %) resulted in an 85% yield (34000 TON) of **5.7** (entry 16, Table 5.3). These are the highest turnovers reported for a β -alkylation system based on Co and are far superior to the best ones reported, also by us very recently.^{9f} In contrast, the corresponding reaction catalyzed by CoCl_2 (0.0025 mol %) resulted in only a 66% yield (ca. 26400 TON) (entry 17, Table 5.3). Subsequent lowering of the catalyst loading of **5.1a** (0.00125 mol %) gave inferior yields (52%, ca. 41600 TON) (entry 18, Table 5.3). Similarly, the β -alkylation carried out at higher loadings of **5.1a** resulted in moderate yields (entries 19 and 20, Table 5.3).

These reactions were associated with formation of black particles that are very similar to the observations reported by us recently and can be attributed to the formation of cobalt nanoparticles (Co NPs) that are inactive due to the fact that the reaction is carried out in air.^{9f} Repeating the β -alkylation with the best composition of **5.1a** (0.0025 mol %) and NaO^tBu (2.5 mol %) at a lower temperature (120 °C) under otherwise identical conditions resulted in reduced yields (35%, ca. 14000 TON) (entry 21, Table 5.3). Negligible reactivity was observed either in the absence of catalyst or in the absence of NaO^tBu (entries 22 and 23, Table 5.3). The total yield of products (**5.6** + **5.7**) was comparable when the reaction was performed in a closed vessel (entry 16 vs entry 24, Table 5.3), which points to alcoholysis as the major

contributor toward product formation (see Plausible Mechanism; *vide infra*). Furthermore, the yields were similar under atmospheres of argon and air (entry 25 vs entry 16, Table 5.3).

^aReaction conditions: 2 mmol of **5.4**, 2 mmol of **5.5**, 2.5 mol% (0.0048 g, 0.05 mmol) of NaO^tBu and 0.0025 mol% of Co catalyst at 140 °C (microwave heating at 75 W) in a closed vessel. ^bThe mol % of base and catalyst is with respect to total alcohol content (**5.4** + **5.5**). ^cYield is determined from ¹H NMR using toluene as a standard. ^dSelectivity = (Yield of **5.7**/ Total yield (**5.6** + **5.7**)) *100 ^e Reaction Performed under 120 °C. ^fPerformed in an open vessel.

Apart from the conventional heating method, under the optimized reaction conditions (entry 16, Table 5.3), the reactions were carried out under the influence of microwave heating (140 °C, 75 W, and 20 psi, Table 5.4). Very similar to our recent observation with Cr-based catalysts,¹³ microwave conditions led to better yields of **5.7** (ca. 83%, 33200 TON at 16600 TO/h) after only 2 h of the reaction (entry 4, Table 5.4). The productivity was poor at lower temperatures (entry 5, Table 5.4) in the **5.1a**-catalyzed reaction under microwave conditions. In comparison to the yields obtained with conventional heating, the yield of β -alkylation with CoCl₂ (0.0025 mol %) under microwave conditions was similar (ca. 61%, 24400 TON) at a much-reduced reaction time (2 h). However, even under microwave conditions, **5.1a** was more efficient than CoCl₂ (entries 4 and 6, Table 5.4).

Using **5.1a** as catalyst, under the best conditions (entry 16, Table 5.3, and entry 4, Table 5.4), the alkylations of several 1- phenylethanol derivatives with variety of benzyl alcohols were carried out under both conventional and microwave heating (Tables 5.5 and 5.6).

Electron-withdrawing and electron-donating groups on benzyl alcohols hardly affected the

^a Reaction conditions unless specified otherwise: 2 mmol of **5.4**, 2 mmol of **5.5**, 2.5 mol% (0.0048 g, 0.05 mmol) of NaO^tBu and 0.0025 mol% (0.00001735 g, 0.00005 mmol) of **5.1a** at 140 °C (conventional heating) for 24 h in an open vessel. ^bThe yield is determined from ¹H NMR using toluene as a standard. ^cAt 140 °C under microwave heating at 75 W for 2 h in a closed vessel.

material, the corresponding yields with pyridin-4-ylmethanol and pyridine-2-ylmethanol (**5.7l** and **5.7e**, Table 5.5) were low.

Very similar to our earlier observations,^{9f,12g} the yield of **5.1a**-catalyzed β -alkylation of 1-phenylethanol with thiophen-2-ylmethanol was better than that of the corresponding reaction with furan-2-ylmethanol (**5.7m** Vs **5.7f**, Table 5.3). Furthermore, **5.1a**-catalyzed β -alkylation of 1-phenylethanol with primary aliphatic alcohols resulted in poor yields (**5.7n–q**, Table 5.3). In stark contrast to the observation with primary alcohols, the presence of electron-withdrawing groups in the *para* position of 1-phenyl ethanol (–F, –Cl, and –NO₂ in **5.7s**, **5.7zd**, **5.7zg** respectively, Table 5.6) leads to lower yields of products. This observation is significant and likely points to the involvement of a methine C–H bond in the RDS (Scheme 5.7 and discussion in Plausible Mechanism, *vide infra*).

With the exception of heteroaromatic secondary alcohols (**5.7z**, **5.7zb**, **5.7zc** and **5.7zk**, Table 5.6) and acyclic aliphatic secondary alcohols (**5.7t**, **5.7zl**, Table 5.6), reasonably good yields were observed for the **5.1a**-catalyzed β -alkylation of most of the 1-phenylethanol derivatives using benzyl alcohol as the alkylating agent (Table 5.6).

5.3.3. Control experiments

We have recently demonstrated that hot-filtration experiments are complementary to a mercury-drop test and that the former could be used as an effective alternate to the hazardous latter.^{9f,13} In the current study it was observed that, heating a mixture of 2 mmol of **5.4**, 2 mmol of **5.5**, 2.5 mol % of NaO^tBu, and 0.0025 mol % of **5.1a** at 140 °C for 24 h under conventional heating conditions resulted in an 85% yield of **5.7** (entry 16, Table 5.3 and equation 1, Scheme 5.6).

In a repeat experiment, the reaction mixture was heated for 1 h and hot-filtered and the filtrate was heated for another 23 h. An analysis of the resulting mixture indicated the formation of **5.7** in 80% yield. The comparable yields of β -alkylation of reactions with (equation 2, Scheme 5.6) and without (equation 1, Scheme 5.6) hot-filtration^{13,17} fortifies the involvement of a well-defined molecular Co catalyst rather than heterogeneous Co.

Furthermore, when **5.4** (2 mmol) and **5.5** (2 mmol) were independently heated at 140 °C with **5.1a** (0.0025 mol %) and NaO^tBu (2.5 mol %) in air for 1 h, the formation of hydrogen

Scheme 5.6. Control Experiments

(Figures 5.8 and 5.9) was detected by GC analysis of the headspace. Trace amounts of benzaldehyde and acetophenone, respectively, were also observed in the ^1H NMR of the reaction mixture. As a trace amount of acetophenone **5.5'** is observed in all of the **5.1a**-catalyzed β -alkylations (Figures 5.S1–5.S66), a control experiment was performed in which **5.5'** was heated with **5.4** under the optimized β -alkylation conditions (equation 5, Scheme 5.6). This led to the formation of **5.6** and **5.7** in 19% and 15% yields, respectively.

The observation of the α,β -unsaturated ketone **5.6'** and hence its possible intermediacy in the reaction was confirmed by heating it with either **5.4** or **5.5**, which served as a sacrificial hydrogen donor under the optimized β -alkylation conditions to yield **5.6** and **5.7**, respectively (equations 6 and 7, Scheme 5.6). More mechanistic insights were obtained from labelling studies by the use of deuterated benzyl alcohol **5.4a**. When a mixture of **5.5** (2 mmol), **5.4** (1 mmol), and **5.4a** (1 mmol) was heated to 140 °C with **5.1a** (0.0025 mol %) and NaO^tBu (2.5 mol %) in an open vessel under air, the β -alkylated product **5.7'** was obtained in 49% yield (equation 8, Scheme 5.6). On the basis of the amount of deuterium incorporation at Ca, the KIE was found to be 6.14.^{9f,11k,12g,13,18}

Valuable information was obtained from following a reaction of **5.4** (2 mmol) and **5.5** (2 mmol) catalyzed by **5.1a** (0.25 mol %) in the presence of NaO^tBu (2.5 mol %) at 140 °C in air by ESR (Figure 5.5) and HRMS (Figure 5.7). Complex **5.1a** is paramagnetic ($\mu_{\text{eff}} = 3.23 \mu_{\text{B}}$ in the solid state and $\mu_{\text{eff}} = 4.29 \mu_{\text{B}}$ in solution), which indicates it to be either octahedral or trigonal bipyramidal.¹⁵ On the basis of an HRMS analysis (Figure 5.3) it is clear that there is actually a mixture of **5.1a** (trigonal bipyramidal) and **5.3a** (octahedral). However, it should be noted that the well-defined ESR signal (Figure 5.5a) arises from only **5.1a** with a trigonal-bipyramidal geometry, as Co(II) in an octahedral geometry is reported to be ESR inactive.^{9f,16} The reaction mixture was ESR silent (Figure 5.5) throughout the reaction, which points to Co(II) species in an octahedral environment.^{9f,16} The paramagnetic nature of these ESR-silent octahedral Co(II) species was confirmed by magnetic moment measurements (Figure 5.6b) by the Evans method. The observed magnetic moment value of $3.04 \mu_{\text{B}}$ ¹⁵ (Figure 5.6b) and the ESR-silent nature^{9f,16} (Figure 5.5b–i) points to the involvement of octahedral Co(II) species^{8–12} **5.8–5.12** (Scheme 5.7). Notably under the reaction conditions both the TBP precursor **5.1** and the O_h/T_h ion pair precursor **5.3** is likely to transform irreversibly to O_h species **5.8–5.12**.

Figure 5.5. ESR spectra of (a) **5.1a** in methanol, (b) reaction mixture containing **5.1a** (0.25 mol %) in a solution of **5.4** and **5.5** immediately after mixing, (c) reaction mixture containing **5.1a** (0.25 mol %) and NaO'Bu (2.5 mol %) in a solution of **5.4** and **5.5** immediately after mixing, (d) reaction mixture containing **5.1a** (0.25 mol %) and NaO'Bu (2.5 mol %) in a solution of **5.4** and **5.5** after heating at 140 °C for 30 min, (e) reaction mixture containing **5.1a** (0.25 mol %) and NaO'Bu (2.5 mol %) in a solution of **5.4** and **5.5** after heating at 140 °C for 1 h, (f) reaction mixture containing **5.1a** (0.25 mol %) and NaO Bu (2.5 mol %) in a solution of **5.4** and **5.5** after heating at 140 °C for 3 h, (g) reaction mixture containing **5.1a** (0.25 mol %) and NaO'Bu (2.5 mol %) in a solution of **5.4** and **5.5** after heating at 140 °C for 5 h, (h) reaction mixture containing **5.1a** (0.25 mol %) and NaO'Bu (2.5 mol %) in a solution of **5.4** and **5.5** after heating at 140 °C for 14 h, (i) reaction mixture containing **5.1a** (0.25 mol %) and NaO'Bu (2.5 mol %) in a solution of **5.4** and **5.5** after heating at 140 °C for 24 h.

At $t = 0$ h (prior to heating), a HRMS analysis (Figure 5.7) of the reaction mixture showed peaks at m/z 338.3429 and 675.6765 that correspond to **5.8a'** and **[5.9a' + H₂O + 2CH₃CN + K]⁺**, respectively, with the former presumably arising from the methoxide for benzyl oxide/1-phenyl ethoxide substitution of **5.8a/5.9a** (when X = OCH₂Ph, OCH(CH₃)Ph, Scheme 5.7) in the methanol solvent used for analysis. When the system is heated for 1 h, apart from the peaks

Figure 5.6. Determination of the magnetic moment of the Co species present in the solution containing **5.1a** (a) before the addition of base and (b) after the addition of base.

observed at 0 h, an additional peak at m/z 419.2005 corresponding to $[\mathbf{5.8a}'' + \text{H}]^+$ was observed in the HRMS analysis. The HRMS analyses at later times (Figures 5.S82–5.S85) were similar to those observed at 1 h. These observations indicate the involvement of well-defined molecular Co(II) species during catalysis, in line with the observations made in equations 1 and 2 (Scheme 5.6). The HRMS analyses are also indicative of the integrity of the pincer fragment and show that the imino groups are intact during catalysis. Furthermore, the similar yields obtained under atmospheres of air and argon (entry 16 vs entry 25, Table 5.3) are indicative of the absence of any redox species (Co(II)/Co(0) or Co(II)/Co(III)) in the catalytic cycle. One should also not ignore the fact that pincer-Co adducts containing the products **5.6** and **5.7** are not observed. This points to their absence in the RDS.

Figure 5.7. HRMS analysis of a mixture of **5.4** (2 mmol) and **5.5** (2 mmol) in the presence of **5.1a** (0.001735 g, 0.005 mmol, 0.25 mol %) and NaO'Bu (0.0048 g, 0.05 mmol, 2.5 mol %) after (a) 0 h and (b) 1h.

5.3.4. Plausible Mechanism

The inferences drawn from control experiments (Scheme 5.6 and Figures 5.5–5.7) have been instrumental in arriving at a plausible mechanism (Scheme 5.7). The NNN pincer-Co complex **5.1/5.3** upon treatment with NaO'Bu in the presence of **5.4/5.5** yields octahedral Co(II) species **5.8/5.9** along with the formation of NaCl (Scheme 5.7). The detection of **5.8a'** and **5.9a'** in the HRMS of the reaction mixture at room temperature suggests that the salt metathesis of **5.1/5.3** with NaO'Bu occurs at room temperature. Subsequent β -hydride elimination from **5.8/5.9** gives the corresponding carbonyl compounds **5.4'/5.5'** and the hydride complex **5.10**. Notably **5.4'** and **5.5'** are detected by NMR in the independent dehydrogenations of **5.4** and **5.5**, respectively (equations 3 and 4, Scheme 5.6). On the other hand, in the Guerbet reaction mixture, only **5.5'** is detected by NMR. The absence of Co adducts with either **5.6** or **5.7** in the HRMS analysis (Figure 5.7) suggests that the rate-determining step (RDS) lies in the alcohol dehydrogenation

alcoholysis/ hydrogenolysis via **5.10** → **5.12** → **5.8/5.9/5.10** can be envisaged for the transformation of **5.6** to **5.7**. If hydrogenolysis is involved, it requires closed-vessel conditions. On the other hand, the reaction is unaffected by either a closed-vessel or open-vessel condition if alcoholysis is involved. In our current studies, apparently, alcoholysis is a major contributor to product (entries 16 and 24, Table 5.3 and entries 4 and 7, Table 5.4) formation and hence not surprisingly the reaction yields are similar under either open-vessel or closed-vessel conditions. Though hydrogen is involved, it is likely to be in a low steady-state concentration and could be rapidly consumed back in a reverse reaction apart from leading to a minor amount of product formation via hydrogenolysis. This is very similar to our recent reports on β -alkylation with CoCl_2 ,^{9f} pincer-Ni,^{12g} and pincer-Cr-based catalysts.¹³

Figure 5.8. Evidence for the evolution of H_2 in dehydrogenation of benzyl alcohol (**5.4**) catalyzed by **5.1a** (0.005 mol %) at 140 °C via GC analysis.

5.4. Conclusion

The environmentally benign, earth-abundant, and inexpensive base metal cobaltous chloride has been used to synthesize pincer-Co complexes of the type $(\text{R}^2\text{NNN})\text{CoCl}_2$ ($\text{R} = i\text{Pr}, t\text{Bu}, \text{Cy}, \text{Ph}, p\text{-F-C}_6\text{H}_4$). On the basis of the nature of the R group, these complexes are found to exist

Figure 5.9. Evidence for the evolution of H₂ in dehydrogenation of 1-phenyl ethanol (**5.5**) catalyzed by **5.1a** (0.005 mol %) at 140 °C via GC analysis.

in equilibrium with the corresponding ion-pair $[(^R\text{2NNN})_2\text{Co}]\text{CoCl}_4$. The TGA analysis indicates that the considered pincer-Co complexes demonstrate very good thermal stability. All of the considered pincer-Co complexes have been found to efficiently catalyze β -alkylation of 1-phenylethanol with benzyl alcohol. In particular, $(^i\text{Pr}^2\text{NNN})\text{CoCl}_2$ has demonstrated the best activity in air at 140 °C. Under conventional heating, $(^i\text{Pr}^2\text{NNN})\text{CoCl}_2$ (0.0025 mol %) catalyzed the β -alkylation in the presence of NaO^tBu (2.5 mol %) in 24 h to yield 85% (34000 TON at 1417 TO/h) of the β -alkylated product. On the other hand, the corresponding reaction under microwave conditions (140 °C at 75 W) was complete in only 2 h with a comparable yield (83%, 33200 TON) and far better TOF (16600 TOs/h). Under similar conditions, the precursor CoCl_2 (0.0025 mol %) gave relatively poor results under both conventional (ca. 66%, 26400 TON at 1100 TOs/h) and microwave heating (ca. 61%, 24400 TON at 12200 TOs/h). The β -alkylations (ca. 39 examples) of a range of secondary alcohols with several primary alcohols have been successfully accomplished using $(^i\text{Pr}^2\text{NNN})\text{CoCl}_2$ as a catalyst under both conventional and microwave heating.

Hot-filtration experiments and HRMS analyses suggest the existence of well-defined molecular Co(II) species during the catalytic β -alkylation. During the reaction Co remains in its +2 state,

as inferred from EPR studies and magnetic moment measurements using the Evans method. In good agreement with HRMS analyses that show pincer-Co adducts only with reactant alcohols and in line with the observation of trace amounts of acetophenone during the β -alkylation, key evidence for the involvement of C–H activation (β -hydride elimination of acetophenone in particular) in the RDS of the pincer-Co-catalyzed reaction is obtained from competitive deuterium labelling experiments that result in a KIE of 6.14. This also explains the low yields of β -alkylation of 1-phenylethanol derivatives with electron-withdrawing groups. To the best of our knowledge, these unprecedented turnovers (33200 TON at 16600 TO/h) in such a short time (2 h) are the best reported hitherto with base-metal catalysis for β -alkylation. These pincer-Co catalytic systems that operate in air under microwave conditions offer exciting possibilities for related tandem (de)hydrogenation reactions.

5.5. Experimental section

5.5.1. General Procedure and Materials

All manipulations were carried out in air. The chemicals NaO^tBu, KO^tBu, NaOH, KOH, Na₂CO₃, K₂CO₃, CDCl₃, benzyl alcohol, 1-phenylethanol, and their derivatives were purchased either from Sigma-Aldrich or MERCK and used as such. All catalytic reactions were carried out in air using oven dried glassware. The 1-phenyl ethanol derivatives that were not commercially available were prepared according to a literature procedure.^{19a} Tetrahydrofuran (THF) was dried via double distillation over Na/benzophenone.

5.5.2. Physical Measurements

The ¹H and ¹³C{¹H} NMR spectra were recorded on a Bruker ASCEND 600 instrument operating at 600 MHz for ¹H and 150 MHz for ¹³C{¹H}, a Bruker AVANCE 500 instrument operating at 500 MHz for ¹H and 125 MHz for ¹³C{¹H}, or a Bruker AVANCE 400 instrument operating at 400 MHz for ¹H and 100 MHz for ¹³C{¹H}. Chemical shifts (δ) are reported in ppm. HRMS measurements were carried out using an Agilent Accurate-Mass Q-TOF ESI-MS 6520 instrument. The X-band EPR spectra were recorded on a JES-FA200 ESR spectrometer. X-ray crystallographic data were acquired on a Bruker D8 Venture single-crystal X-ray diffractometer using graphite-monochromated Mo K α radiation. The data refinement and cell reductions were carried out with the Bruker SAINT program.²⁰ Structures were further solved and refined by the full-matrix least-squares method using SHELXS-14.²¹ Thermogravimetric analyses were performed using a thermal analyser (SDTQ600) with a simultaneous DTA/TGA

system, under argon with a heating rate of 10 °C min⁻¹. Solid-state magnetic susceptibilities of the complexes were recorded using a Sherwood Scientific MSB-1 magnetic balance at room temperature. Microwave reactions were carried out with a CEM Discover apparatus operating at a voltage of 110 V and microwave irradiation of 2.45 GHz with a maximum microwave output of 300 W.

5.5.3. Synthesis of (ⁱPr₂NNN)CoCl₂ (5.1a)

The metal salt CoCl₂ (0.045 g, 0.346 mmol) was stirred with the ligand **5.2a** (0.075 g, 0.346 mmol) in dry and distilled THF (3 mL) for 16 h at room temperature. The solvent was evaporated under reduced pressure, and the light green solid was washed with diethyl ether (3 × 3 mL). The residue was dried under vacuum and isolated as a light green solid (0.103 g) in 86% yield. HRMS (ESI): *m/z* calculated for [**5.3a** - CoCl₄]²⁺ = [C₂₆H₃₈CoN₆]²⁺ 246.6245, found 246.6250; *m/z* calculated for [**5.1a** - Cl]⁺ = [C₁₃H₁₉ClCoN₃]⁺, 311.0600, found 311.0593; *m/z* calculated for [**5.1a** - Cl + CH₃CN + 3H₂O]⁺ = [C₁₅H₂₈ClCoN₄O₃]⁺, 406.1182, found 406.1107; *m/z* calculated for [**5.1a'** + 2CH₃CN + 3H₂O + Na]⁺ = [C₁₇H₃₃CoN₅NaO₅]⁺, 469.1891, found 469.1711. Magnetic susceptibility: $\mu_{\text{eff}} = 3.23 \mu_{\text{B}}$.

5.5.4. Synthesis of (^tBu₂NNN)CoCl₂ (5.1b)

The metal salt CoCl₂ (0.065 g, 0.5 mmol) was stirred with the ligand **5.2b** (0.129 g, 0.5 mmol) in dry and distilled THF (3 mL) for 16 h at room temperature. The solvent was evaporated under reduced pressure, and the green solid was washed with diethyl ether (3 × 3 mL). The residue was dried under vacuum and isolated as a green solid (0.146 g) in 78% yield. HRMS (ESI): *m/z* calculated for [**5.1b** - Cl]⁺ = [C₁₅H₂₃ClCoN₃]⁺, 339.0913, found 339.0907; *m/z* calculated for [(^tBu₂NNN)Co(OH)(OCH₃) + 2CH₃CN + H]⁺ = [C₂₀H₃₄CoN₅O₂]⁺ 435.2045, found 435.3767. Magnetic susceptibility: $\mu_{\text{eff}} = 4.42 \mu_{\text{B}}$.

5.5.5. Synthesis of (^{Cy}2NNN)CoCl₂ (5.1c)

The metal salt CoCl₂ (0.045 g, 0.346 mmol) was stirred with the ligand **5.2c** (0.103 g, 0.346 mmol) in dry and distilled THF (3 mL) for 16 h at room temperature. The solvent was evaporated under reduced pressure, and the blackish green solid was washed with diethyl ether (3 × 3 mL). The residue was dried under vacuum and isolated as a blackish green solid (0.126 g) in 43% yield. HRMS (ESI): *m/z* calculated for [**5.3c** - CoCl₄]²⁺ = [C₃₈H₅₄CoN₆]²⁺, 326.6871,

found 326.6866; m/z calculated for $[5.1c - Cl]^+ = [C_{19}H_{27}ClCoN_3]^+$, 391.1226, found 391.1221. Magnetic susceptibility: $\mu_{\text{eff}} = 3.51 \mu_B$.

5.5.6. Synthesis of $(\text{Ph}_2\text{NNN})\text{CoCl}_2$ (5.1d)

The metal salt CoCl_2 (0.045 g, 0.346 mmol) was stirred with the ligand **5.2d** (0.099 g, 0.346 mmol) in dry and distilled THF (3 mL) for 16 h at room temperature. The solvent was evaporated under reduced pressure, and the yellow solid was washed with diethyl ether (3×3 mL). The residue was dried under vacuum and isolated as a yellow solid (0.129 g) in 90% yield. HRMS (ESI): m/z calculated for $[5.3d - \text{CoCl}_4]^{2+} = [C_{38}H_{30}CoN_6]^{2+}$ 314.5932, found 314.5943; m/z calculated for $[5.1d - Cl]^+ = [C_{19}H_{15}ClCoN_3]^+$, 379.0287, found 379.0281. Magnetic susceptibility: $\mu_{\text{eff}} = 4.09 \mu_B$.

5.5.7. Synthesis of $(p\text{-F-C}_6\text{H}_4)_2\text{NNN})\text{CoCl}_2$ (5.1e)

The metal salt CoCl_2 (0.045 g, 0.346 mmol) was stirred with the ligand **5.2e** (0.111 g, 0.346 mmol) in dry and distilled THF (3 mL) for 16 h at room temperature. The solvent was evaporated under reduced pressure, and the yellow solid was washed with diethyl ether (3×3 mL). The residue was dried under vacuum and isolated as a yellow solid (0.144 g) in 93% yield. HRMS (ESI): m/z calculated for $[5.1e - Cl + 3\text{CH}_3\text{OH} + \text{CH}_3\text{CN}]^+ = [C_{24}H_{28}ClCoF_2N_4O_3]^+$, 552.1150, found 552.3152. Magnetic susceptibility: $\mu_{\text{eff}} = 4.19 \mu_B$.

5.5.8. General Procedure for 5.1a-Catalyzed β -Alkylation of Alcohols

In a 10 mL pear-shaped flask containing 1-phenylethanol and benzyl alcohol were added 2.5 mol % of NaO^tBu and 0.0025 mol % of $(i\text{Pr}_2\text{NNN})\text{CoCl}_2$ (from a stock solution in either 1-phenylethanol or benzyl alcohol). Ultimately, the reaction mixture contained 0.0347 mg (0.1 μmol) of $(i\text{Pr}_2\text{NNN})\text{CoCl}_2$, 9.6 mg (0.1 mmol) of NaO^tBu , 0.241 mL (2.00 mmol) of 1-phenylethanol, and 0.206 mL (2.00 mmol) of benzyl alcohol. The contents were heated at 140 $^\circ\text{C}$ (either under conventional heating for 24 h or under microwave (75 W) for 2 h) in air and subsequently cooled to room temperature. A known amount of toluene was then added to the reaction mixture. From the reaction mixture, an aliquot (10 mg) was withdrawn and the ^1H NMR recorded in CDCl_3 . The yield (in mmol) of product formed was calculated from ^1H NMR using a known amount of toluene as a standard.^{19b} The percentage yield was obtained by multiplying the ratio of calculated yield to theoretical yield by 100.

Supporting information (containing NMR spectra and of reaction mixtures, HRMS data, GC plot, TGA data, EPRS data) for chapter V is available as appendix IV and can be found at https://drive.google.com/file/d/1nRhWgF9bdDny5-1W_ZrfScmF2e7tI0ZP/view?usp=sharing

Summary and outlook

CHAPTER -II

CHAPTER -III

CHAPTER -IV

CHAPTER -V

Chapter-I discusses the use of pincer complexes as efficient catalysts for various transformations. Pincer-metal complexes, due to their robust nature and high thermal stability, have been at the forefront in the dehydrogenation of alkanes and alcohols. Further, the use of alcohols as alkylating agent with various substrates using these complexes has been reviewed. The chapter ends with the discussion of the scope of the current thesis.

Chapter-II deals with the synthesis and characterization of three new NNN pincer-ruthenium complexes based on *bis*(imino)-pyridine ligands. These complexes in addition to their 2,6-*bis*(benzimidazol-2-yl)pyridine counterparts have been further applied towards the β -methylation of 2-phenylethanol and selective β -dimethylation of 1-phenylethanol using methanol as an alkylating agent. Among all the considered complexes, the pincer-ruthenium complex $[(^{\text{MeBim}2}\text{NNN})\text{RuCl}(\text{PPh}_3)_2]\text{Cl}$ exhibited the best catalytic activity. The complex $[(^{\text{MeBim}2}\text{NNN})\text{RuCl}(\text{PPh}_3)_2]\text{Cl}$ (0.5 mol %) catalyzed the β -methylation of 2-phenylethanol in presence of 0.75 equivalents of KOH and 7.5 equivalents of methanol, resulting in 92% yield of β -methylated alcohol at 140 °C after 24h. Further, the selective β -dimethylation of 1-phenylethanol was achieved in presence of $[(^{\text{MeBim}2}\text{NNN})\text{RuCl}(\text{PPh}_3)_2]\text{Cl}$ (0.5 mol %) with 2 equivalents of Na using 24.8 equivalents of methanol at 140 °C to obtain β -dimethylated alcohol with 92% yield and 92% selectivity. The kinetic experiments showed the linear dependence of rate of product formation on the concentrations of both 2-phenylethanol and the pincer-ruthenium catalyst. The reaction was catalyzed by well-defined molecular catalysts as inferred from the mercury-drop test and kinetic studies. The kinetic isotope effect studies were performed, where a secondary KIE of 1.56 was obtained. The σ -bond metathesis of methanol with the Ru-H species with concomitant evolution of hydrogen is the RDS with a barrier of 24.06 kcal/mol as inferred from the DFT calculations.

Figure 1: [$(^{\text{MeBim}^2\text{NNN}}\text{RuCl}(\text{PPh}_3)_2)\text{Cl}$] catalyzed β -methylation of 2-phenylethanol and 1-phenylethanol.

Chapter-III discusses a series of new and previously known NNN pincer-Ru catalysts of the type $(^{\text{R}^2\text{NNN}}\text{RuCl}_2\text{L})$ ($\text{R} = \textit{i}\text{Pr}, \textit{t}\text{Bu}, \text{Cy}, \text{Ph}, p\text{-F-C}_6\text{H}_4, p\text{-OMe-C}_6\text{H}_4$ and $\text{L} = \text{PPh}_3, \text{CO}$ and CH_3CN) based on *bis*(imino)pyridine ligands and [$(^{\text{RBim}^2\text{NNN}}\text{RuClL}_2)\text{Cl}$] ($\text{R} = \text{H}$ and Me , $\text{L} = \text{PPh}_3$ and CO) based on 2,6-*bis*(benzimidazole-2-yl)pyridine ligands. All complexes were tested for the decarboxylative coupling of lower-molecular weight alcohols to higher-molecular weight alkanes. The $(^{\text{MeBim}^2\text{NNN}}\text{RuCl}_2(\text{PPh}_3)_2)$ (1 mol%) based on 2,6-*bis*(benzimidazole-2-yl)pyridine ligand catalyzed the decarboxylation of 2-phenylethanol in presence of 0.5 equivalents of NaOH to produce 91% of 1,3-diphenyl propane with 100% selectivity at 140 °C within 5 hours. The first-order dependence of initial rate on both the concentration of base and catalyst concentration was inferred from the kinetic studies. The DFT calculations were in accordance with the experimental findings and indicate that the dehydrogenolysis step leading to the formation of 2-phenyl acetaldehyde and the resting state $(^{\text{MeBim}^2\text{NNN}}\text{RuHCl})$ is the rate-determining step with a barrier of 22.81 kcal/mole at 140 °C. In comparison to the rate-determining dehydrogenolysis step of the cycle involving most active catalyst [$(^{\text{MeBim}^2\text{NNN}}\text{RuCl}(\text{PPh}_3)_2)\text{Cl}$], the corresponding cycle with the least active catalyst $(^{\text{iPr}^2\text{NNN}}\text{RuCl}_2(\text{PPh}_3))$ involved insertion of 1,3-diphenyl propene into the Ru-H bond as the RDS which is kinetically unfavorable by 5.00 kcal/mol and gives only 14% of 1,3-diphenyl propane at 25% selectivity. To the best of our knowledge, this is the first example of a Ru based

catalyst for the upgradation of alcohols to alkanes directly without the need of an additional hydrogenation step.

Figure 2: $[(\text{MeBim}^2\text{NNN})\text{RuCl}(\text{PPh}_3)_2]\text{Cl}$ catalyzed deoxygenative coupling of alcohols to alkane.

Chapter-IV describes the use of readily available CoCl_2 that forms complexes with alcohols *in-situ* and efficiently catalyzes the β -alkylation of alcohols under air. The rapid formation of heterogeneous cobalt NPs was observed in the presence of 1 mol% of CoCl_2 , which were sensitive to air, resulting in poor yields (25%) of β -alkylated products. When the reaction was carried out with 0.01 mol% of CoCl_2 , a better control over reactivity (87% yield, *ca.* 8700 TON) was observed with the delay in the heterogenization. The kinetic experiments exhibited the linear dependence of rate of the product formation on the concentrations of both, cobaltous chloride (in the regime of homogeneity) and sodium *tert*-butoxide. Further, the concentration of 1-phenyl ethanol and benzyl alcohol showed a non-linear dependence on the rate of the product formation. The superior reactivity for the β -alkylation of alcohols was observed with molecular Co catalysts rather than heterogeneous Co NPs. The possible involvement of C–H activation in the cobaltous chloride catalyzed β -alkylation was inferred from the deuterium labelling experiments with a $k_{\text{H}}/k_{\text{D}}$ value of 1.61.

Figure 3: CoCl_2 catalyzed β -alkylation of secondary alcohols with primary alcohols.

Chapter-V discuss the use of earth-abundant, inexpensive, environmentally benign base metal cobaltous chloride to synthesize pincer-Co complexes of the type $(\text{R}^2\text{NNN})\text{CoCl}_2$ ($\text{R} = i\text{Pr}, t\text{Bu}, \text{Cy}, \text{Ph}, p\text{-F-C}_6\text{H}_4$). These complexes are found to exist in equilibrium with the corresponding ion-pair $[(\text{R}^2\text{NNN})_2\text{Co}]\text{CoCl}_4$ depending on the nature of the R group. The high thermal stability of considered pincer-Co complexes was tested using TGA analysis. Among the considered complexes, $(i\text{Pr}_2\text{NNN})\text{CoCl}_2$ demonstrated the best activity in air under both thermal and microwave heating at 140°C for the β -alkylation of secondary alcohols with primary alcohols. The $(i\text{Pr}_2\text{NNN})\text{CoCl}_2$ (0.0025 mol %) complex in the presence of 2.5 mol% of $\text{NaO}t\text{Bu}$ gave 85% (34000 TON at 1417 TO/h) of the β -alkylated product in 24 h under conventional heating. On the other hand, the same reaction under microwave conditions (140°C at 75 W) was accomplished within 2 h with a comparable yield of 83% (33200 TON) with a better TOF of 16600 TOs/h. Upon using CoCl_2 with similar reaction conditions, poor results under both conventional (ca. 66%, 26400 TON at 1100 TOs/h) and microwave heating (ca. 61%, 24400 TON at 12200 TOs/h) were observed. The existence of well-defined molecular Co(II) species formed during the catalytic β -alkylation was proved by HRMS analysis and hot-filtration experiments. The EPR studies and magnetic moment measurements using the Evans method, pointed towards the presence of octahedral cobalt in +2 oxidation state. The C-H activation (β -hydride elimination of acetophenone in particular) is the RDS, which was

confirmed from HRMS analysis and competitive deuterium labelling experiments that result in a KIE of 6.14.

Figure 4: ($i\text{Pr}_2\text{NNN})\text{CoCl}_2$ catalyzed β -alkylation of secondary alcohols with primary alcohols.

The current thesis has explored the synthetic methodologies to arrive at new pincer-Ru and pincer-Co complexes based on *bis*(imino)pyridine and 2,6-*bis*(benzimidazol-2-yl)pyridine ligands. These pincer complexes have been utilized for various organic transformations with a special emphasis towards the transformation of alcohols to value-added chemicals. Attempts have been made to attain systematic understanding of reaction mechanism wherever possible.

The finding of the thesis could open new route for the synthesis of fuels, organic reaction intermediates, fine chemicals and value-added chemicals from readily available alcohols.

Due to high selectivity, high efficiency and increased reaction rate, the catalytic reactions are of utmost importance in the industrial sectors. They enable the transformation of several raw materials into various value-added commodities, by lowering the activation energy while simultaneously cutting down on the costs. Studying their catalytic activity and understanding the underlying mechanism of various consider pincer-metal systems throughout the chapters of this thesis, it is obvious that several challenges remains and need to be addressed, such as

1. Can one activate the small molecules like N_2 , CO_2 using the most effective and efficient pincer-ruthenium catalyst based on *bis(imino)pyridine* or *bis(benzimidazole-2-yl)pyridine* ligand system?
2. Is it possible to heterogenize these pincer-ruthenium and pincer-cobalt complexes for catalytic recyclability?
3. Is it possible to design better catalyst and perform the reactions which have been studied throughout the thesis under milder reaction conditions for safe and efficient catalytic process?
4. Can one design catalytic system based on *bis(benzimidazole-2-yl)pyridine* ligands that employ Co(I) or Co(II) that can show high efficiency for such challenging organic transformations?

Overall there is a need of designing a catalytic system consisting of earth abundant metals which is less sensitive, air stable, environmentally benign and which is highly efficient towards catalytic value-addition of alcohols under mild reaction conditions.

Curriculum Vitae **Pran Gobinda Nandi, IIT Guwahati**

Phd student

Department of Chemistry

Indian Institute of Technology, Guwahati,

Guwahati-781039, Assam, India

Academic Background

Doctor of Philosophy (PhD) in Chemistry from Indian Institute of Technology, Guwahati, (2018-2024), Assam, India under the supervision of Dr. Akshai Kumar A.S.

Thesis title: *Pincer-Ruthenium and Pincer-Cobalt Catalyzed Value-Addition of Alcohols.*

MSc Chemistry in Inorganic Specialization from Jadavpur University, West Bengal, India. (2015-2017).

BSc (H) Chemistry from Kandi Raj College, University of Kalyani, West Bengal, India. (2012-2015).

Research Interest

1. Catalysis
2. Organometallics chemistry
3. Inorganic synthesis
4. DFT calculation

Conferences Attended

- **Nandi, P. G.;** Kumar, A. Poster presentation during 30th International Conference on Organometallic Chemistry, ICOMC, Agra, India, July **2024**. “Pincer-Ruthenium-Catalyzed β -Methylation of Alcohols”.
